PIPOR (Program for International Polar Oceans Research) Finland project examines the use of ERS-1 SAR (Synthetic Aperture Radar) in sea ice mapping in the Baltic Sea through geophysical validation and demonstration. The experimental part was performed in Jan. - Mar. 1992. The winter was very mild which caused restrictions in all planned activities. Two expeditions were made with an airborne program and ground truth. In the demonstration phase, near real time SAR imagery was provided to users. ERS-1 SAR data are also used in ice dynamics modeling. The first results show that ERS-1 SAR is an excellent complement to the existing ice mapping routine. ESA

During the period Jan. - Mar. 1992 the Baltic Experiment for ERS-1 (BEERS-92) was carried out in the Gulf of Bothnia. The purpose of the experiment was: to carry out field measurements on various types of ice in time for ERS-1 over passes; to demonstrate the usefulness of ERS-1 SAR (Synthetic Aperture Radar) images in an operational Sea Ice Service; and for icebreaker operations. For the experiment a BDDN (Broadband Data Dissemination Network) receive station was installed where SAR images were processed, disseminated, and stored. The field program, carried out from an icebreaker, consisted of in situ sea ice measurements and of helicopter photography. The emphasis was on sea ice parameters relevant for radar scattering investigations, i.e surface roughness, ice, and snow physics. Preliminary analysis of the SAR images shows a wide range of radar signatures mainly related to surface roughness variations. The demonstration experiment included the use of SAR images by the operational Sea Ice Service and the transmission of processed SAR images to icebreakers in near real time. ESA

GREENLAND SEA OBSERVATIONS

P. Gudmandsen, H. Buch Mortensen, L. Toudal Pedersen, H. Skriver, and P. Minnett (Brookhaven National Lab., Upton, NY.) *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 319-323 Sponsored by BNL and Danish Space Research Inst. (For primary document see N94-11704 01-43) (Grant NSF DPP-91-13962)
Copyright Avail: CASI HC A01/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

ERS-1 SAR (Synthetic Aperture Radar) data was acquired over the Greenland Sea and Fram Strait during two periods, the ice phase of three day repeat cycle from Jan. to Mar. 1992 and a one month period in the 35 day repeat cycle from 16 Jul. to 15 Aug. 1992. Most data became available by way of the Broadband Data Dissemination System, with a spatial resolution of about 100 m. With these data various algorithms were tested to derive sea ice parameters such as ice extent, ice concentration and ice displacement. In the latter period data were collected to support the activities of a research vessel in the area mainly related to the large polynyas that form east and north of Greenland. The formation of polynyas could clearly be outlined but other phenomena were also observed related to the influence of wind streets and gravity waves associated with the atmospheric boundary layer. The data will have to be studied further, including full resolution data to substantiate the conclusions. ESA

Studies on the validation and utilization of ERS-1 SAR (Synthetic Aperture Radar) derived liquid and solid ocean information and the study of the interregional, regional, and temporal variation of the microwave signatures of sea ice and snow, are reported. Initial interests are focused on the accuracy of the estimates of ice type, ice form, deformation state, or thickness, and the ability to retrieve ice physical property information. Two in situ campaigns were conducted for the purpose of 'truth' ERS-1 SAR products and to gather data in support of the above science studies. ESA

C-BAND SAR BACKSCATTER FROM ICE ON SHALLOW TUNDRA LAKES: OBSERVATIONS AND MODELLING
H. Wakabayashi, M. O. Jeffries (Alaska Univ., Fairbanks.), and W. F. Weeks (Alaska Univ., Fairbanks.) *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 333-337 (For primary document see N94-11704 01-43)
Copyright Avail: CASI HC A01/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

The pronounced backscatter variations observed in sequential ERS-1 SAR (Synthetic Aperture Radar) images of tundra lakes near Barrow, Alaska are investigated. Earlier work suggested that weak returns could be attributed to attenuation of the radar signal where the ice was frozen to the lake bed, and strong returns to forward scattering off bubbles in the ice in combination with a near specular ice water interface. Field measurements in Apr. 1992 confirmed this hypothesis. At the locations sampled, grounded ice was less than 1 m thick while free floating ice exceeded 2 m. As long as the ice remained bubble free, backscatter values were low (-20 dB). When tubular bubbles appeared, these values rose to -9 to -10 dB and then gradually increased to values as high as -6 dB. Where the ice froze to the lake bed, values dropped to -18 dB. A numerical model of C band backscatter from such lake ice covers was also developed. A preliminary comparison between the modeled and observed backscatter is presented. ESA

SEA ICE RADAR SIGNATURES FROM ERS-1 SAR DURING LATE SUMMER AND FALL IN THE BEAUFORT AND CHUKCHI SEAS
Benjamin Holt, Glenn Cunningham, and Ron Kwok *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 339-342 Sponsored by NASA, Washington (For primary document see N94-11704 01-43)
Copyright Avail: CASI HC A01/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

A study which examines ERS-1 C band SAR (Synthetic Aperture Radar) imagery of sea ice obtained in the Beaufort and Chukchi Seas from mid Summer through Fall freeze up and early Winter in 1991 is presented. Radar backscatter statistics of sea ice were obtained from the imagery, using common floes tracked through consecutive repeat images whenever possible. During the Summer months, strong fluctuations in ice signatures of several dB are observed over 2 to 3 day periods, which are found to be closely related to air temperature excursions above and below freezing that alters the phase of the ice surface. As air temperatures drop steadily below freezing in the Fall, the signatures of the pack ice increase in brightness and become more stable with time. Multiyear ice is distinguished from rough and smooth first year ice. There are also variations in the multiyear signatures with latitude. Large variations are seen in new ice and open water contained within leads which results in ambiguous classification. ESA

THE SEASONAL SEA ICE MONITORING AND MODELLING SITE (SIMMS): USING ERS-1 IN CLIMATE RESEARCH Abstract Only
Ellsworth F. LeDrew and David G. Barber *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 349 (For primary document see N94-11704 01-43)
Copyright Avail: CASI HC A01/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

The Seasonal Sea Ice Monitoring and Modeling Site (SIMMS) experiment is introduced and the use of ERS-1 data to develop a better understanding of radiative, turbulent, and conductive fluxes which operate at the ocean-sea ice-atmosphere interface, is described. The objective is to understand the magnitude and rate of change of the major physical fluxes which occur between the ocean, sea ice, and atmosphere. ERS-1 data are the primary remote sensing data being used in the SIMMS experiment. The rationale for selection of ERS-1 data, the scales over which the surface validations are being conducted, and the theory behind how microwavelength radiance can be linked to climatological shortwave interaction and hence be of value in numerical studies of climate processes, are described. Preliminary results showing how the relative scattering cross section can be used to infer the climatological shortwave albedo over the seasonally varying snow covered sea ice surface are given in conclusion. ERS-1 SAR (Synthetic Aperture Radar) images and airborne SAR and SLAR (Side Looking AR) images were collected from the ice covered region over the Labrador and Newfoundland (Canada) shelves in Feb. and Mar. 1992. In the ERS-1 SAR images, very new ice (grease ice) is shown dark, and open water filled with wind waves is very bright. Airborne electromagnetic measurements combined with a laser and an altimeter clearly demonstrate ice thicknesses variable in space and may provide calibration data for the SAR data. Once ice floes are tracked between two images, ice velocity field will be constructed and used for detecting ocean currents under the ice cover. ESA

PRELIMINARY EVALUATION OF ERS-1 SAR DATA FOR OPERATIONAL USE IN THE CANADIAN SEA ICE MONITORING PROGRAM

Mohammed E. Shokr, Bruce Ramsay (Ice Centre Environment Canada, Ottawa, Ontario.), and John C. Falkingham (Ice Centre Environment Canada, Ottawa, Ontario.) *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 355-360 (For primary document see N94-11704 01-43)

Copyright Avail: CASI HC A02/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

A preliminary evaluation of ERS-1 SAR (Synthetic Aperture Radar) data for operational use in the Canadian ice monitoring program was conducted. The analysis was based on manual image interpretation by ice analysts in the Ice Center Environment Canada. A potential for operational use of SAR data exists although it was not fully demonstrated. Ice types and surface features can be extracted successfully from images of fully consolidated ice. Image interpretation is not easy for summer ice and open pack ice. The frequency of satellite coverage does not match frequency of events in ice. Limitations on the use of data are presented along with recommendations to relax them. ESA

SEA ICE FEATURE AND TYPE IDENTIFICATION IN MERGED ERS-1 SAR AND LANDSAT THEMATIC MAPPER IMAGERY

K. Steffen, J. Heinrichs, J. Maslanik, and J. Key *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 361-365 (For primary document see N94-11704 01-43)

(Grant NAGw-2598)

Copyright Avail: CASI HC A01/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

LANDSAT Thematic Mapper (TM) and ERS-1 SAR (Synthetic Aperture Radar) C band images were acquired for the same area in the Beaufort Sea, 18 Apr. 1992. The two images were co-located to the same grid (25 m resolution) and supervised classification was performed on the TM channel 3 scene in order to classify open water, nilas, grey ice, first year ice, and multiyear ice. Comparison of the LANDSAT classification and the corresponding dB values from the SAR scene showed that, under the given circumstances (high surface winds), open water/nilas/grey ice as defined by a single ice category by the SAR classifier could not be distinguished from first year ice. Surface roughening due to wind appears to be a major problem for the SAR classifier, as the range of the dB values is large enough to overlap all the other ice categories. Additional information, such as surface wind speed is necessary to overcome part of this problem. ESA

SUMMER ARCTIC ICE CONCENTRATIONS AND CHARACTERISTICS FROM SAR AND SSM/I DATA

Joey C. Comiso and Ron Kwok (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 367-372 (For primary document see N94-11704 01-43)

Copyright Avail: CASI HC A02/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

The extent and concentration of the Summer minima provide indirect information about the long term ability of the perennial portion of the ice pack to survive the Arctic atmosphere and ocean system. Both active and passive microwave data were used with some success for monitoring the ice cover during the Summer, but they both suffer from similar problems caused by the presence of meltponding, surface wetness, flooding, and freeze/thaw cycles associated with periodic changes in surface air temperatures. A comparative analysis of ice conditions in the Arctic region using coregistered ERS-1 SAR (Synthetic Aperture Radar) and SSM/I (Special Sensor Microwave/Imager) data was made. The analysis benefits from complementary information from the two systems, the good spatial resolution of SAR data, and the good time resolution of and global coverage by SSM/I data. The results show that in many areas ice concentrations derived from SAR data are significantly different (usually higher) than those derived from passive microwave data. Additional insights about surface conditions can be inferred depending on the nature of the discrepancies. ESA

EVALUATING ERS-1 ICE MOTION AND CLASSIFICATION PRODUCTS

F. Fetterer and D. Gineris (Sverdrup Technology, Inc., Bay Saint Louis, MS.) *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 373-375 Sponsored by NRL (For primary document see N94-11704 01-43)

Copyright Avail: CASI HC A01/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

ERS-1 Synthetic Aperture Radar (SAR) imagery from the Alaska SAR Facility is available to operational ice analysts at the Joint Ice Center. Analysts can use the imagery directly through manual interpretation. One such use would be to provide information on ice conditions for a field expedition. In addition, analysts can run automated algorithms which produce estimates of ice type and ice motion from SAR images. Such automated analysis will become increasingly important if SAR is to be used to improve climatologies of ice characteristics and to improve the performance of dynamic ice models. The ice classification and ice motion algorithms developed for ERS-1 SAR imagery are evaluated and results presented. ESA

THE HEIGHT CALIBRATION OF THE ERS-1 RADAR ALTIMETER

C. R. Francis *In its* Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 381-393 (For primary document see N94-11704 01-43)

Copyright Avail: CASI HC A03/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

During Aug. and Sep. 1991 a coordinated campaign of many different types of measurements was made in order to perform a height calibration of the ERS-1 Radar Altimeter (RA). This followed extensive preparatory campaigns over the previous years. The basic scenario required the satellite to overfly a small oceanographic research platform in the northern Adriatic Sea, off the shore from Venice. This was surveyed into the same network as a set of European Satellite Laser Ranging (SLR) stations, by a series of GPS campaigns. Additionally a new site for a mobile SLR station was established in the area. Local measurements of sea level were made at the platform during the overflights, together with additional environmental measurements. Following the measurement campaign all of the data sets, including the altimeter data themselves, were carefully processed and cross checked against other data sources, where possible, to ensure consistency. Eventually it was possible to determine the bias in the altimeter measurements to a high level of accuracy. ESA

FIRST RESULTS FOR THE SIMULTANEOUS ESTIMATION OF THE GEOID AND THE SEA SURFACE TOPOGRAPHY BY ERS-1 ALTIMETER DATA

N. Arent, G. Hueckelheim, and K. R. Koch *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 395-399 (For primary document see N94-11704 01-43)

(Contract BMFT-01-QS-8901)

Copyright Avail: CASI HC A01/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

The geoid and the sea surface topography are simultaneously estimated by ERS-1 altimeter data in an area of the North Atlantic containing the Gulf stream east of the coast of the U.S. The method is based on a quasi-geostrophic model by which the sea surface topography is represented. Orbital errors are accounted for by a bias and tilt for each arc running through the area of investigation. Prior information is introduced for all unknown parameters, for the geoid undulations, for the streamfunctions of the quasi-geostrophic model and for the biases and tilts, which leads to a Kalman filter for estimating the parameters. Two steps of the Kalman filter are applied to analyze 35 days of ERS-1 data. The results indicate improvements of the geoid in the area of investigation. ESA

Regional mesoscale marine geoids of horizontal scales between x(sub h) greater than or equal to 60 km and less than or equal to 100 km using ERS-1 radar altimeter data were analyzed. For this investigation three different sea areas, the North Sea, the Baltic Sea, and the Indonesian waters are selected. To point out the main characteristics causing sea level changes in the three study areas, an overview is given. A proposed analysis scheme is presented. Due to this concept, instantaneous sea surface heights and predicted geoid heights are required. A first statistical analysis of ERS-1 ocean product altimeter data is given, due to the relative sparse coverage of the study areas during the 3 day repeat cycle. This analysis supplies selection criteria which are needed to avoid measurement biases influencing the data quality. ESA

A STOCHASTIC-DETERMINISTIC APPROACH AS AN ALTERNATIVE TO CLASSICAL CROSS-OVER TECHNIQUES IN SMALL OCEAN BASINS
L. Fenoglio and E. Groten *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 407-411 (For primary document see N94-11704 01-43)
(Contract DFG-GR-361/30-1)
Copyright Avail: CASI HC A01/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

A stochastic deterministic approach to sea surface determination combining altimetry and tide gauge data is discussed. These two methods were combined to improve upon the poor performance of stand-alone altimetry methods. The method is applied to Geosat real data. One repeat cycle of 17 days is considered. The test area chosen is the western Mediterranean Sea because the sea surface height values for a set of tide gauges stations were available. The geometrical stability of the solution is tested using simulated Geosat data. A solution for the sea surface topography and its estimated accuracy are presented. ESA

AN ANALYSIS OF THE GRAVITY FIELD IN THE NORWEGIAN SEA AND MAPPING OF THE ICE CAP OF GREENLAND USING ERS-1 ALTIMETER MEASUREMENTS
C. C. Tscherning, P. Knudsen (National Survey of Denmark, Copenhagen.), S. Ekholm (National Survey of Denmark, Copenhagen.), and O. Baltazar Andersen (National Survey of Denmark, Copenhagen.) *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 413-418 Sponsored by Danish Space Board (For primary document see N94-11704 01-43)
Copyright Avail: CASI HC A02/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Recent ERS-1 altimeter data were used to recover the gravity field in the Norwegian Iceland Greenland Sea. The spectral characteristics of the gravity field were investigated from 18 arcs of 3 day repeat period data. The recovered gravity field correlates exclusively with the major geological structures. This clearly demonstrates the potential of the new ERS-1 altimeter data. For land applications, ERS-1 altimetry has completed a monitoring of the ice sheet in Greenland up to 82 deg. The first digital elevation model was constructed from altimeter data with an almost complete coverage of the ice sheet. ESA

SPACE AND TIME VARIABILITY OF THE GULF STREAM USING ERS-1 ALT-OPR02 DATA **c48**
J.-F. Minster, C. Brossier, M.-C. Gennero, S. Houry, and P. Vincent *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 419-423 (For primary document see N94-11704 01-43)
Copyright Avail: CASI HC A01/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

The ERS-1 OPR-02 (Ocean Product) altimeter data from 1 Sep. - 9 Dec. 1991 was analyzed. In the North Atlantic Ocean, along-track wavenumber spectra of the mesoscale variability are very consistent with those derived from 2 years of Geosat data. They indicate a noise of 4 to 4.5 cm and a space resolution from 90 to 150 km. In the Gulf Stream area, the height variability derived from 3 months of ERS-1 3 day repeat data is comparable to that derived from 2 years of Geosat 17 day repeat data, while it is slightly lower elsewhere. Indeed, ERS-1 samples more of the high frequency variability of the Gulf Stream but less of the lower frequency mesoscale signal elsewhere. This is confirmed by 3, 6, and 9 day isocorrelation maps. ESA

REMOVAL OF ORBITAL ERROR AND THE LOCAL GEOID EFFECTS FROM ERS-1 ALTIMETER DATA
M. M. Ali and Rashmi Sharma *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 425-430 (For primary document see N94-11704 01-43)
Copyright Avail: CASI HC A02/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Sea surface height data, obtained from the altimeters, are subject to many sources of errors, unlike the other two parameters: wind speed and the significant wave height. Orbital error can be removed by subtracting the individual satellite heights from the quadratic fit. The fluctuations remaining after this are due to the local geoid effects and can be removed by subtracting the individual passes from a reference pass over the same track. ERS-1 altimeter data was analyzed. The maximum radial orbital error is found to be about 80 m. ESA

Zandbergen (Logica Ltd., London, England.) *In its* Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 431-437 (For primary document see N94-11704 01-43)
Copyright Avail: CASI HC A02/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

In parallel with the routine operational orbit determination and control activities associated with the ERS-1 Mission Management and Control Center (MMCC), a precise orbit solution based on laser tracking and altimetry is generated at ESOC. This provides a valuable check on the quality of the MMCC orbit and is also compared from time to time with the D-PAF (German Processing and Archiving Facility) preliminary orbit. A comprehensive history since launch of all three solutions is presented. Both MMCC and laser solutions include continuous monitoring of the unmodeled altimeter bias, the results of which are consistent and stable to within a few cm. Work on improving the modeling of the altimetry as a tracking type has concentrated on determining a mean sea surface model (with respect to an adopted geoid). Of special interest is the extent of coherency of these solutions with respect to time. ESA

ERS-1 RADAR ALTIMETRY OVER THE NORTH ATLANTIC **c48**
K. F. Wakker, E. Wisse, M. C. Naeije, R. Scharroo, P. N. A. M. Visser, and B. A. C. Ambrosius *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 439-444 Sponsored by Space Research Organization Netherlands and Beleidscommissie Remote Sensing (For primary document see N94-11704 01-43)
Copyright Avail: CASI HC A02/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Recent ERS-1 (35 day repeat) altimetric measurements over the north Atlantic were processed to study the mean sea surface and the sea surface currents. Some details on the processing techniques used and on the results obtained are presented. The large scale semi-permanent circulation is determined from a least squares parameter adjustment method in which a number of gravity field coefficients and a low degree and order dynamic ocean topography model are solved simultaneously. After radial orbit error reduction by crossover difference residuals minimization, the variable mesoscale circulation is obtained from analyzing the temporal variation of the local sea surface. In addition, mean wavenumber spectra were computed for two areas in the north atlantic. ESA

THE EFFECT OF RAIN ON ERS-1 ALTIMETER DATA

T. H. Guymer and G. D. Quartly *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 445-450 (For primary document see N94-11704 01-43)
Copyright Avail: CASI HC A02/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Atmospheric liquid water, particularly in the form of rain, can produce anomalies in altimeter data. A preliminary investigation into such features in the ERS-1 dataset was conducted using sudden, large changes in radar backscatter as a means of identification. Most occurred in tropical latitudes. It is found that there is a close relationship between the existence of altimeter anomalies and a liquid water correction derived from the passive microwave instrument on ERS-1. However, the correction accounts for only 20 percent of the observed effects. Some of the altimeter passes exhibit enhanced backscatter and waveheight features which are probably caused by distortion of the pulse shape. One pass through Hurricane Andrew was also examined in which heavy rain appears to have caused the altimeter to lose lock. ESA

The German Processing and Archiving Facility for ERS-1 (D-PAF) is in charge of computing Preliminary (PRL) and Precise (PRC) orbits. These tasks have been performed since the launch of ERS-1 on 17 Jul. 1991. The precision orbit determinations are mainly based on Satellite Laser Ranging (SLR) data from a global tracking network. To enable the SLR stations to track ERS-1, orbit predictions have to be generated and distributed, which is also done by D-PAF. On a weekly basis PRL orbits are computed from laser quick look and radar altimeter fast delivery data and disseminated within one week. The PRC orbits are generated after reception of the laser full rate data. For the three different orbit types, the status is presented and quality estimates are shown. ESA

PRELIMINARY GEOPHYSICAL INVESTIGATION WITH ERS-1 35-DAY ALTIMETER DATA

A. Cazenave, S. Houry, K. Dominh, and M. C. Gennero *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 457-462 Sponsored by CNES (For primary document see N94-11704 01-43)
Copyright Avail: CASI HC A02/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

ERS-1 altimeter data of the first 35 day cycle provided by the National Ocean Service at NOAA were interpolated and gridded at a global scale to recover mean sea surface heights. A regional analysis was also performed over the south central Pacific combining ERS-1 and Geosat profiles to increase the coverage. Some geoid features are discussed. ESA

An overall review of the Arctic Geodynamics project is presented. A composite gravity field model of the region based upon altimetry data from ERS-1, Geosat, and Seasat is made. ERS-1 altimetry covers unique Arctic and Antarctic latitudes above 72 deg. Both areas contain large continental shelf areas, passive margins, as well as recently formed deep ocean areas. Until ERS-1 it was not possible to study these areas with satellite altimetry. Gravity field solutions for the Barents sea, portions of the Arctic ocean, and the Norwegian sea north of Iceland are shown. The gravity anomalies around Svalbard (Spitsbergen) and Bear island are particularly large, indicating large isostatic anomalies which remain from the recent breakup of Greenland from Scandinavian. Recently released gravity data from the Armed Forces Topographic Service of Russia cover a portion of the Barents and Kara seas. A comparison of this data with the ERS-1 produced gravity field is shown. ESA

QUICK-LOOK MONITORING OF THE SEA SURFACE WITH ERS-1 FAST DELIVERY ALTIMETER DATA

T. Spoecker, M. Anzenhofer, W. Bosch (Deutsches Geodaetisches Forschungsinst., Munich, Germany.), and T. Gruber *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 469-472 Prepared in cooperation with Academy of Sciences, Potsdam, Germany (For primary document see N94-11704 01-43)
Copyright Avail: CASI HC A01/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

For the ERS-1 mission, ESA provides altimeter fast delivery products that are available within three hours after measurement. The data consist of time tagged altimeter altitude, wind speed, and significant wave height completed by atmospheric corrections. Use and analysis at the German Processing and Archiving Facility (D-PAF) indicate that the altimeter data, when combined with preliminary satellite ephemerides, can be very well used for a quick look monitoring of the sea surface. For this purpose a preliminary orbit, generated at D-PAF by means of globally acquired laser tracking data is merged into the fast delivery altimeter data. In addition, Earth and ocean tides are computed, atmospheric corrections are improved, orbit error adjustment and digital sampling techniques are used to generate a series of quick look sea surface height models. These new products span a time period of 35 days (one repeat cycle) and are processed every week. They compile sea surface heights, an estimate of the rate of change of the sea surface as well as resampled wind speed and wave heights averaged for the same period of time. ESA

The German ERS-1 Processing and Archiving Facility (D-PAF) is charged by ESA to provide the global Earth's gravity field model for ERS-1 precise orbit determination and altimeter data reduction. The just delivered ERS-1 Gravity Model, EGM1, which is dedicated to the ERS-1 commissioning phase (Jul. - Dec. 1991), is based on the most recent non-ERS-1 GRIM4 satellite-only model. The GRIM4 gravity models are elaborated within the long term German/French cooperation. The accuracy of the EGM1 gravity model is estimated in terms of geoid undulations and crossover differences. The quality is evaluated by satellite test arc computations. ESA

ERS-1 PRECISE ORBIT DETERMINATION

R. Scharroo, K. F. Wakker, B. A. C. Ambrosius, R. Noomen, W. J. vanGaalen, and G. J. Mets *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 477-482 (For primary document see N94-11704 01-43)

Copyright Avail: CASI HC A02/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Various aspects of the computation of ERS-1 orbits incorporated on the NOAA ERS-1 IGDR's, the effects of selecting an improved gravity model, the ways to assess the orbit accuracy, and the orbit improvements to be obtained from incorporating altimeter range data in the orbit computation, are addressed. The operational ERS-1 orbits using the NASA/GSFC GEM-T2 gravity model appear to have a radial accuracy of about 140 cm, whereas the GSFC PGS-4591 model already delivers orbits with a radial accuracy of about 35 cm. The best SLR (Satellite Laser Ranging) solutions obtained so far, however, have a radial precision of about 22 cm, and they are based on the GSFC PGS-4988 gravity model including the estimation of a 1 cpr along track acceleration. Incorporating altimeter range measurements as tracking data in the orbit determination can bring this figure down to 19 cm. ESA

VALIDATING THE UK-PAF LAND ICE PRODUCT SURFACE ELEVATION

D. R. Mantripp and J. K. Ridley *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 483-488 (For primary document see N94-11704 01-43)

Copyright Avail: CASI HC A02/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

The UK-PAF (Processing and Archiving Facility) ERS1.ALT.LIR product is designed to provide users with measurements of geophysical parameters over continental ice sheets. The PAF philosophy of providing fully calibrated and validated products extends to these data, and as part of this process a series of field experiments were carried out in Jan./Feb. 1992 on Filchner Ice Shelf, Antarctica. The objectives of the fieldwork were to obtain calibrating/validation data for ice shelf elevation and radar backscatter. The preliminary work towards establishing a method for external calibration of surface elevation is discussed. Two subsatellite track test areas were established, one on the ice shelf itself nearby Berkner Island, and one on the Coats Land plateau, at 500 m above sea level. Surface profiles were obtained from GPS (Global Positioning System) kinematic surveying. One GPS profile from Filchner ice shelf, coinciding with a subsatellite track from the 35 day repeat mission, was compared with ERS-1 Radar Altimeter 3 day repeat raw data and 35 day repeat URA products. Altimeter derived surface elevation was calculated using restituted orbit data. The GPS elevation data are found to lie within 1 m of the URA data and within 5 m of the 3 day repeat raw elevation data. While the results are not yet good enough to provide validation data to targeted accuracies, they will be improved significantly with more sophisticated analysis and further field data. ESA

GLOBAL WAVE HEIGHT CLIMATOLOGIES FROM ERS-1 ALTIMETER DATA, AND COMPARISONS WITH THOSE FROM GEOSAT

D. J. T. Carter *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 489-492 (For primary document see N94-11704 01-43)

Copyright Avail: CASI HC A01/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Global monthly mean significant wave height data (H(sub s)) in 2 deg latitude by 2 deg longitude bins are estimated from Geosat and from the ERS-1 altimeter. The data are analyzed to see whether a cross calibration of the two altimeters can be obtained. The ERS-1 fast delivery data from Jan. - Jun. 1992 are used. The principal component fits for the same months of different years indicate a consistent difference between the data sets from the two satellites, from which a linear relationship between Geosat and ERS-1 estimates of H(sub s) is derived. A preliminary check of monthly mean H(sub s) values from ERS-1 against buoy data suggests an inconsistency, which can only be resolved by further validation. ESA

SPATIAL SCALES OF WAVE HEIGHT c48

Peter G. Challenor *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 493-498 Sponsored by Health and Safety Executive (For primary document see N94-11704 01-43)

Copyright Avail: CASI HC A02/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Using Geosat data it is shown that the along-track spectrum of significant wave height is invariant across the world oceans. This spectrum can be represented by three (or possibly two) power laws. When spectra from Geosat ERS-1 fast delivery and ERS-1 offline data are examined, there are differences particularly between Geosat and ERS-1. These differences are examined and it is hypothesized that they are due to differences in the trackers onboard the satellites. The offline data is reprocessed on the ground and therefore does not contain the effect of any tracker. It thus should give the 'true' spectrum. ESA

LATENT AND SENSIBLE HEAT FLUX ESTIMATED FROM ERS-1 DATA

S. F. Iacobellis and C. Gautier (California Univ., Santa Barbara.) *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 499-503 Sponsored by NASA, Washington and California Univ. (For primary document see N94-11704 01-43)

Copyright Avail: CASI HC A01/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Two issues regarding surface latent and sensible heat flux are addressed: its value in low wind speed conditions over the tropical oceans,and its determination solely from satellite observations. The investigation is performed with an oceanic mixed layer model operated in an 'inverse' mode. The 'normal' model is forced with the surface heat and radiative fluxes and produces the SST evolution, whereas the 'inverse' model produces the latent sensible heat flux given the SST and surface radiative flux as input. The results indicate that at low wind speeds there exists a minimum latent sensible heat flux of about 80 to 100 W/sq m. Sensitivity studies show that the latent sensible heat flux is very sensitive to random errors in the forcing SST time series. The implications of this strong sensitivity in regards to the use of satellite measurements to supply the forcing SST are discussed. ESA

USING TRANSPONDERS WITH THE ERS-1 ALTIMETER TO MEASURE ORBIT ALTITUDE TO +/- 3 cm

R. J. Powell, A. R. Birks, W. J. Bradford, C. L. Wrench, and J. Biddiscombe *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 511-516 (For primary document see N94-11704 01-43)

Copyright Avail: CASI HC A02/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Analysis suggests that, by deploying an active transponder on land beneath a satellite altimeter it should be possible to make a measurement of the height of the satellite as it passes over the transponder with an accuracy equal to or better than that with which the altimeter can measure the range to the sea surface, +/- 1 to 3 cm. Early progress in successfully demonstrating the basic altimeter to transponder measurement technique by deploying transponders beneath the ERS-1 satellite is reported, preliminary experiments to assess the technique are described, and some potential applications are identified. ERS-1 altimeter data at the Fast Delivery Copy (FDC) format from the 3 day repeat mission were analyzed to demonstrate mesoscale eddy features around the Gulf Stream. The analysis procedure is: to interpolate sea surface height at regular grids; to remove time average mean heights at the grids; and to remove a quadratic curve fit to height structures on an approximately 2000 km long arc. It was shown that the FDC may be useful for observing energetic mesoscale features at mid latitudes. A striking feature is a high anomaly captured on the track only for 10 days. Since the data from the descending tracks are clean, ERS-1 data will give cross track resolution higher than Goesat in the Gulf Stream and the Kuroshio regions. ESA

EFFECTS OF SATELLITE SPECTRAL RESOLUTION AND ATMOSPHERIC WATER VAPOR ON RETRIEVAL OF NEAR-GROUND TEMPERATURES
Alan E. Lipton 28 Apr. 1993 12 p
(AD-A264920; AD-E201523; PL-TR-93-2101) Avail: CASI HC A03/MF A01

One of the challenges in remote sensing of surface temperatures for meteorological applications is to distinguish clearly the influence of the ground surface on the measured radiances from the influence of the overlaying atmosphere. It is common, particularly in cloud-free situations, to have large differences in temperature over very short vertical distances from the ground up through the lowest kilometer of the atmosphere. The research to be presented focused on the vertical resolution capabilities of the VISSR Atmospheric Sounder (VAS) and the proposed GOES High-Resolution Interferometer Sounder (GHIS) in this lowest part of the temperature profile. Results of simulated retrievals and experiments on the sensitivity of radiances to profile perturbations indicated that, for a moderately moist atmosphere, ground surface temperature errors of about 1 C and low-level air temperature errors of about 3 C can occur in VAS retrievals due specifically to vertical resolution limitations and instrument noise. For a drier atmosphere the surface temperature errors tend to be smaller and the low-level air temperature errors tend to be larger. These values do not account for other sources of retrieval error, such as interference by clouds, uncertainty of the ground surface emittance, or deficiencies in the radiative transfer computation method. EFFECT OF SPECIES STRUCTURE AND DIELECTRIC CONSTANT ON C-BAND FOREST BACKSCATTER
R. H. Lang (George Washington Univ., Washington, DC.), R. Landry (Canada Centre for Remote Sensing, Ottawa, Ontario.), O. Kilic (George Washington Univ., Washington, DC.), N. Chauhan, N. Khadr (George Washington Univ., Washington, DC.), and D. Leckie (Petawawa National Forestry Inst., Chalk River, Ontario.) 1993 4 p
(NASA-TM-109219; NAS 1.15:109219) Avail: CASI HC A01/MF A01

A joint experiment between Canadian and USA research teams was conducted early in Oct. 1992 to determine the effect of species structure and dielectric variations on forest backscatter. Two stands, one red pine and one jack pine, in the Petawawa National Forestry Institute (PNFI) were utilized for the experiment. Extensive tree architecture measurements had been taken by the Canada Centre for Remote Sensing (CCRS) several months earlier by employing a Total Station surveying instrument which provides detailed information on branch structure. A second part of the experiment consisted of cutting down several trees and using dielectric probes to measure branch and needle permittivity values at both sites. The dielectric and the tree geometry data were used in the George Washington University (GWU) Vegetation Model to determine the C band backscattering coefficients of the individual stands for VV polarization. The model results show that backscatter at C band comes mainly from the needles and small branches and the upper portion of the trunks acts only as an attenuator. A discussion of variation of backscatter with specie structure and how dielectric variations in needles for both species may affect the total backscatter returns is provided. Author (revised)

SAMPLING AND POSITION EFFECTS IN THE ELECTRONICALLY STEERED THINNED ARRAY RADIOMETER (ESTAR)
Stephen J. Katzberg Aug. 1993 17 p
(RTOP 476-14-15-01)
(NASA-TM-108998; NAS 1.15:108998) Avail: CASI HC A03/MF A01

A simple engineering level model of the Electronically Steered Thinned Array Radiometer (ESTAR) is developed that allows an identification of the major effects of the sampling process involved with this technique. It is shown that the ESTAR approach is sensitive to aliasing and has a highly non-uniform sensitivity profile. It is further shown that the ESTAR approach is strongly sensitive to position displacements of the low-density sampling antenna elements. Author

SEGMENTED LAND USE CLASSIFICATION OF MULTITEMPORAL ERS-1 SAR DATA USING A MAJORITY FILTER
J. Kellndorfer, R. Schadt, and W. Mauser *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 523-526 (For primary document see N94-12471 01-43)
Copyright Avail: CASI HC A01/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Twenty-eight ERS-1 single look complex scenes of the commissioning phase of ERS-1 in the time period 17 Aug. to 30 Nov. 1991 of the Freiburg test site (Upper Rhine Valley (Germany)) were converted to greyvalue images that were speckle reduced using a Lee filter and geometrically matched. A maximum likelihood classification of the testsite (approximately 50 sq km) was performed. The classes, buildings/villages, water, forest, corn, and meadows/fallow fields were compared with a digital land use map resulting from the 1991 ground data collection. As can be expected, speckle still influences the classification results. To overcome this problem the classification result was fitted to the digital field boundary map. This enabled a fieldwise postclassification using the majority rule which considerably improved the result of the multitemporal land use classification. ESA

LAND COVER MONITORING WITH MULTI-TEMPORAL ERS-1 SAR OBSERVATIONS IN THE NETHERLANDS
G. J. A. Nieuwenhuis and C. G. J. Schotten *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 527-531 (For primary document see N94-12471 01-43)
Copyright Avail: CASI HC A01/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Since the launch of the ERS-1 satellite in Jul. 1991, Synthetic Aperture Radar (SAR) C band images have been obtained on a regular basis. A calibrated SAR image taken on 7 Sep. 1991 was evaluated. It was found that for different land cover types, reliable backscatter values were obtained. Multitemporal images, acquired during the first three months after the launch of the satellite, were applied to perform a land cover mapping experiment. To solve the speckle problem of the applied SAR images, a field based classification method was used. The first results are very promising and they show the great potential of ERS-1 SAR images to monitor land cover. Crop classification accuracy varied from 60 to 90% for spring barley (already harvested at the acquisition dates) and potatoes, respectively. Fruit trees, often difficult to classify with images taken in the shortwave range of the spectrum, were classified correctly for about 75%. Following the land cover mapping experiment in a later stage, land cover information will be combined with crop growth simulation results to forecast crop yield. ESA

MAPPING A DYNAMIC PLAYA SURFACE USING MULTITEMPORAL ERS-1 SAR DATA: FIRST RESULTS
G. Wadge, A. C. Millington, and D. J. Archer *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 533-538 Sponsored by Natural Environmental Research Council, United Kingdom (For primary document see N94-12471 01-43)
Copyright Avail: CASI HC A02/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

The mapping of Chott el Djerid in north central Tunisia, a flat salt playa whose surface composition and micromorphology are highly dynamic, is considered. The ERS-1 Active Microwave Instrument (AMI) Synthetic Aperture Radar (SAR) is sensitive to temporal changes in roughness and moisture, and geocoded images from May and Aug. 1992 show within and between scene changes in backscatter of the order of 10 dB. These changes are the result of the interplay of the processes of temporary lake formation and evaporation, capillary evaporation, surface water flow, and aeolian transport and deposition. A multitemporal sequence of SAR images with a field monitoring program of roughness and moisture measurement will provide a quantitative test of the ability to understand backscatter change in terms of these processes. ESA

ERS-1 ALTIMETRY OF INLAND WATER AND LAND
C. G. Rapley, S. G. Baker, C. M. Birkett, S. W. Laxon, J. K. Ridley, R. F. Scott, and F. Strawbridge *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 539-542 (For primary document see N94-12471 01-43)
Copyright Avail: CASI HC A01/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

In order to extract useful information from satellite radar altimeter data acquired over inland water and land, considerable insight into the response of a pulse limited altimeter to a complex, topographic surface is required. Also, except over continuous water surfaces, it is essential to process the echo waveforms, both to eliminate erroneous data points, and to match the data analysis technique to the echo characteristics of the surface. The use of ERS-1 altimeter fast delivery (non-echo) data to provide an initial overview of the global data set is described. The work relies on a new data filtering scheme designed to eliminate erroneous data points. Preliminary results using a limited quantity of waveform data are reported. ESA

PRELIMINARY STUDIES ON THE APPLICATION OF ERS-1 DATA TO TOPOGRAPHIC MAPPING
I. Dowman, M. Upton, J. deKnecht, and C. Davison *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 543-549 (For primary document see N94-12471 01-43)
Copyright Avail: CASI HC A02/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

A geocoding system was developed and used to geocode ERS-1 Synthetic Aperture Radar (SAR) images with the aim of using the data for topographical applications. The results are presented. A validation scheme is part of the system and this includes the production of shadow, layover, and energy conservation maps. Cultural features were extracted from the data and compared to existing maps. The use of speckle reduction filters was investigated and the results indicate that the level of information which can be extracted is low without supporting map data. If existing data is used then new features can be identified and mapped. Height was extracted from ERS-1 data using stereoscopic methods. Stereoscopic data were obtained from overlapping scenes from adjacent orbits and from the roll tilt mode. Preliminary results are presented showing that stereo matching can be applied on the overlapping images with the same incidence angle at the scene center and from images with different incidence angles from the roll tilt mode. ESA

First results of the project to produce a radarmap of Germany are described. Specific software was developed to fulfill the special requirements for interpretation of Synthetic Aperture Radar (SAR) images. A new approach was developed and implemented on a Stardent computer. A mosaiking tool, the Mosaiking Mask Editor (MME), was designed and realized on a SUN computer together with an expert system shell. With this software it is possible to combine different ERS-1 scenes. The standard input images are SUN raster image files. This software was tested with different Seasat and ERS-1 images. Various data sources are in use for this project. The main input data are terrain corrected ERS-1 SAR data. To extract special auxiliary information, a digital terrain model was integrated into the classification system. Different cartographic parameters are used by the MME. The results of the Col's are integrated. ESA

Preliminary results of an assessment of the use of ERS-1 SAR (Synthetic

Aperture Radar) data for land use mapping in a savannah zone of West Africa are presented. Optical data (LANDSAT, SPOT) were compared with microwave data (SIR-A, ERS-1). LANDSAT Thematic Mapper data were initially geocoded with a Digital Terrain Model (DTM) and then registered to ERS-1 data. Standard and adaptive filters were applied to SAR data and the results compared. Two methods of optical/microwave data integration were tested. It appeared that land use classes identification was not satisfactory using single date ERS-1 data. Good results were obtained in the case of a multitemporal SAR approach and particularly when combining dry season optical data with rainy season SAR data.

With the many optical data available from various remote sensing platforms (LANDSAT, SPOT) and the recent ERS-1 Synthetic Aperture Radar (SAR) satellite data, it is critical to be able to register, compare and analyze these different data if full advantage is to be made from the multiplicity of information sources. An example of SPOT/ERS-1 complementarity is given. The main differences between SPOT and ERS-1 are described and a practical application illustrated by a project called 'production of SPOT/ERS image maps on a scale of 1/50,000' is developed. Focus is on the technical aspects of the specific geocoded products generation process, in particular, the radiometry and geometry. Limitations and constraints are discussed.

A study to determine the potential use of ERS-1 Synthetic Aperture Radar (SAR) data for agrohydrological applications, based on the relation between the radar response and superficial soil moisture, is reported. The study is based on the comparison of satellite data with measurements done in the field and other catographic information. The remote sensing radar was combined with other sources of geographical information, to locate regions susceptible to drought and to flooding and to determine the morphology of the land. In order to be integrated into the geographic information system, the ERS-1 images were geometrically rectified. Details of the material and method used and first data analysis results and conclusions are given.

SNOW AND GLACIER INVESTIGATIONS BY ERS-1 SAR: FIRST RESULTS
H. Rott and Th. Nagler *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 577-582 Sponsored by Oesterreichische Akademie der Wissenschaften (For primary document see N94-12471 01-43)
Copyright Avail: CASI HC A02/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

The backscattering behavior of snow and glacier ice was investigated using 12 ERS-1 Synthetic Aperture Radar (SAR) scenes acquired over the test site Otztal in the Austrian Alps between Apr. and Oct. 1992. Significant temporal changes of the backscattering coefficient were observed, which were mainly caused by variations in liquid water content of the snowpack and in the roughness of snow and ice surfaces, as confirmed by field measurements of structural and dielectric properties. Corner reflectors deployed on the firn areas of the glaciers, provide useful reference for geometric corrections and for radiometric calibration. ERS-1 SAR images show good capabilities for monitoring the areal extent of wet snow on glaciers and ice free areas and for detecting the snowline on glaciers. Digital techniques for snow and glacier mapping by means of ERS-1 SAR data are in progress.

A method was developed to make ERS-1 Synthetic Aperture Radar (SAR) a suitable, operational tool for high mountain geoecological studies. It is based on a very precise geocoding using a high resolution Digital Elevation Model (DEM); on radiometric corrections to minimize topographic effects by a pixelwise computation of the local incidence angle, using various backscatter models; and by creating a new synthetic ERS-1 product, containing the fully interpretable SAR information by combining the interpretable parts of an ascending scene with the one of a timely close descending path. For the classification of snow, snowpack, and snow water equivalent and additional geoecological units, correlations with optical satellite data and ground measurements applying data fusion techniques are performed. The evaluation of the results will reveal the possibilities and limitations of ERS-1 for snowpack monitoring in mountainous terrain.

Preliminary results from a 3 year program to investigate the feasibility of the ERS-1 Synthetic Aperture Radar (SAR) to remote sensing of snow are presented. The main goals of the program are to determine: the capability of the ERS-1 SAR to map snow cover, especially melting snow; the effect of forest canopies to SAR snow mapping; and the usefulness of complementing SAR data with other satellite and airborne data types (microwave radiometer and optical data).

Reasons why the use of spaceborne radar imagery would lead to more detailed mapping of a river network in a tropical forest region than other methods (aerial photography and LANDSAT Thematic Mapper) are discussed and a future project to do this in Venezuela is mentioned. No results of this project were present at the time of printing. Basic principles of ERS-1 Synthetic Aperture Radar (SAR) imagery interpretation to delineation of river networks are outlined and further development of the methodology of the project are addressed.

PER-FIELD FILTERING AND CLASSIFICATION OF MULTITEMPORAL ERS-1 SAR IMAGERY
Annick Grillet, Herman Eerens, and Roland Gombeer *In* ESA, Proceedings

of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 605-609 Prepared in cooperation with Service de la Programmation de la Politique Scientifique, Brussels, Belgium (For primary document see N94-12471 01-43)
Copyright Avail: CASI HC A01/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

The heavy speckle noise intrinsic to ERS-1 SAR-imagery strengthens the need for spatial smoothing filters. This pilot study departs from external information on the parcel boundaries in order to apply a per-field filtering. Three different per-pixel classifiers are evaluated: decision tree, maximum likelihood, and nonparametric Bayes. When applied on preliminary filtered image data, the maximum likelihood yields an accuracy of 83% well classified pixels. ESA

PRELIMINARY ERS-1 ASSESSMENT FOR CANADIAN AGRICULTURE AND FORESTRY APPLICATIONS
R. J. Brown, B. Brisco (INTERA Technologies Ltd., Nepean, Ontario.), F. Ahern, S. Yatabe (Petawawa National Forestry Inst., Chalk River, Ontario.), and J. Drieman (Drieman Curtis, Inc., Corner Brook, Newfoundland.) *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 611-616 (For primary document see N94-12471 01-43)
Copyright Avail: CASI HC A02/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

The use of ERS-1 data for agriculture and forestry applications in Canada is addressed. The preliminary results demonstrate the imagery can be used to separate crop types for a test site in Manitoba. The ERS-1 data of a test site in Ontario also contain information about variable soil moisture but surface roughness effects are still present at the steep incidence angle and must be accounted for. Forestry test sites in Ontario and Alberta demonstrate confusion of clear cuts and forested areas on ERS-1 data but good separability on Almaz and airborne Synthetic Aperture Radar (SAR) data. This was attributed to the steep incidence angle of ERS-1 rather than the polarization or frequency differences of the sensors. Promising results in detecting burned areas with ERS-1 data of a test site in Labrador were obtained. ESA

SEGMENTATION AND CHANGE DETECTION IN ERS-1 IMAGES OVER EAST ANGLIA
S. Quegan, R. G. Caves, K. D. Grover, and R. G. White (Defence Research Agency, Malvern, England.) *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 617-622 (For primary document see N94-12471 01-43)
Copyright Avail: CASI HC A02/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

ERS-1 images gathered two months apart from an agricultural region near Feltwell (UK) were analyzed using automatic segmentation based on an iterative edge detection and segment growing method which progressively learns the structure in the image. The images show great structural change, though there is little corresponding variation on the ground; the apparent change in structure is because of large relative changes in the backscatter of fields. Results of segmentation were compared with visual inspection and indicate that the algorithms appear to preserve all the relevant features present in the original data. Over segmentation is more of a problem, which is combatted by removing edges from the original segmentation on the basis of a measure of confidence in the existence of an edge. The segmented images provide a quantitative assessment of the structure in the image, which can be used for comparison and change detection purposes. The striking changes between images serve to emphasize that only by combining images and/or other data sources will a reliable picture of true ground structures be built up. Modifications in order to improve segmentation performance are much clarified by this initial study. ESA

The first experimental phase of the crop monitoring experiment, whose aim is to examine the feasibility of large area crop monitoring by Synthetic Aperture Radar (SAR) by studying the imaging of a restricted range of crops on a variety of soil types, is addressed. Four agricultural experiment sites in East Anglia (UK) were monitored by the ERS-1 SAR through the 1992 growing season. In situ data were collected on the structural and moisture properties of crops and soil in selected fields, concentrating particularly on wheat and sugar beet. A C band ground based scatterometer was used to monitor the backscatter variations of a particular wheat field with a temporal spacing finer than that provided by ERS-1. Statistical analyses of the radar and in situ data are about to commence. A further experiment will be planned for the 1993 growing season. ESA

The possibility of integrating ERS-1 data into the European project of agriculture statistics (Action 4) is investigated. The objective of Action 4 is the rapid estimation of crop surface and potential yield at European level. The estimation of surface and production of crops (within the whole season) is performed with the help of high resolution satellite data of LANDSAT or SPOT over 53 selected sites (40 by 40 km) representing the Commission for the European Community agriculture. In order to test the use of ERS-1 data, three data sets were used over Seville (Spain), one of the Action 4 test sites. A visual interpretation of mono/multitemporal data sets is shown. First results of SPOT/ERS-1 merge are presented. ESA

During the Summer season 1991 intensive ground data collection was carried out on 7 fields within a test site in the Upper Rhine valley (Germany) to continuously record soil moisture in 4 different depths and to weekly measure agricultural plant parameters (leaf area index, biomass, height) of different crops. The high temporal resolution of the ERS-1 Single Look Complex (SLC) radar data of almost 3 days during the commissioning phase in the period of 17 Aug. to 30 Nov. 1991 enabled the continuous documentation of the change of radar backscatter with changing surface features. Correlations between the different plant and soil parameters and the averaged backscatter from the fields under investigation were calculated. ESA

The ability of C band ERS-1 Synthetic Aperture Radar (SAR) data to detect near surface soil moisture was examined over parts of Agra district (U.P. State, India). The ERS-1 SAR data of 9 Dec. 1991 (orbit No. 2081) was evaluated for this purpose. The SAR derived DN (backscatter) values were linearly correlated with near surface soil moisture (0 to 5 cm depth) for bare soil, mustard crop covered soil and combined data set. The value of correlation coefficient was 0.82 for bare soil, 0.89 for mustard covered soil and 0.79 for combined data set. The models were applied to Kiraoli taluka to map the soil moisture distribution. ESA

N94-12493# Remote Sensing Applications Consultants, Farnborough (England).

TEMPORAL MONITORING OF SOIL MOISTURE USING ERS-1 SAR DATA

M. G. Wooding, G. H. Griffiths, R. Evans, P. J. Bird (Defence Research Agency, Farnborough, England.), D. R. D. Kenward (Defence Research Agency, Farnborough, England.), and G. E. Keyte (Defence Research Agency, Farnborough, England.) *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 641-648 (For primary document see N94-12471 01-43)

A program of soil and crop measurements, undertaken during the ERS-1 commissioning phase as part of the UK Synthetic Aperture Radar (SAR) calibration experiment on the test site at Romney Marsh, Kent, is addressed. On 9 overpass days detailed measurements of soil moisture and surface roughness were made in 3 bare soil and 3 grass fields used for corner reflector deployment. Surveys were also undertaken on 5 of these days to record crop type and soil conditions in another 150 agricultural fields. A total of 18 ERS-1 precision images acquired during the 3 day repeat orbit were used. These images were coregistered with a digital map of field boundaries to extract the mean backscatter for sample fields. Accurate calibration of the backscatter measurements was achieved using correction factors derived from the analysis of corner reflector target responses. Analysis of ERS-1 backscatter for the bare soil fields with corner reflectors shows very high positive correlation with volumetric soil moisture over the range 10 to 40 percent. In contrast, there is no correlation between ERS-1 backscatter and the soil moisture for the 3 grass fields with corner reflectors. Temporal backscatter profiles for the sample fields over the 18 imaging dates show large changes in backscatter. Overall trends in ERS-1 backscatter are dominated by moisture effects. Daily and hourly rainfall data are used in conjunction with the detailed soil moisture measurements to explain the temporal profiles for different cover types. Between field variation in ERS-1 backscatter on individual dates is shown to be related to cover type and surface roughness conditions. ESA

OBSERVATIONS OF ERS-1 SAR SENSITIVITIES TO CHANGES IN ABOVEGROUND BIOMASS IN YOUNG LOBLOLLY PINE FORESTS

E. S. Kasischke, N. L. Christensen, Jr. (Duke Univ., Durham, NC.), L. L. Bourgeau-Chavez, and E. Haney (Duke Univ., Durham, NC.) *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 653-656 (For primary document see N94-12471 01-43)

Copyright Avail: CASI HC A01/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

The sensitivity of the microwave return recorded by the ERS-1 C band Synthetic Aperture Radar (SAR) to changes in above ground woody biomass in young loblolly pine forests (dry weight biomass less than 6 kg/sq m) was evaluated. Radar backscattering coefficients were derived from ERS-1 SAR imagery collected over 11 test stands near Durham, North Carolina. Ground truth data were collected in order to characterize the aboveground biomass of the pine trees in the test stands. A significant (at $p = 0.001$) linear correlation (r) was found between the radar backscattering and the various components of biomass (both wet and dry weight) within the pine canopy (for example, bole biomass, stem biomass, needle biomass, canopy biomass and total biomass). The linear correlation coefficients ranged between 0.87 and 0.93. ESA

SEEING THE BLACK FOREST BY ERS-1 AND AIRSAR: A COMPARISON

Carlo Lavalle and Alois J. Sieber *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 657-660 (For primary document see N94-12471 01-43)

Copyright Avail: CASI HC A01/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

During the Summer and the Autumn of 1991 the Black Forest (Germany) was surveyed by two unique Synthetic Aperture Radar (SAR) systems: the C band SAR on board the ERS-1 and the polarimetric SAR on board the AIRSAR. This provided the opportunity to monitor the area for a long period, from Jun. to Nov. 1991. Although the two sensors present sensible differences in the basic imaging characteristics, the collected images were useful in the study of the temporal evolution of the radar backscattering from forested and non forested areas of the region. The forest return showed a dynamic range of about 5 dB over the seven months period, but in the Oct. survey the range was reduced to about 2 dB. The unforested areas, either agricultural fields or clear cut areas, showed a large variation over the observed period and it resulted that the discrimination forest/non forest was not always possible. THE TREES PROJECT: PRE-PROCESSING AND GENERATION OF TERRAIN DATA FOR INCLUSION IN AN ERS-1 SAR CLASSIFICATION SCHEME

A. Sowter, H. DeGroof (Joint Research Centre of the European Communities, Ispra, Italy.), and A. J. Sieber (Joint Research Centre of the European Communities, Ispra, Italy.) *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 665-670 Sponsored by Joint Research Center of the European Communities (For primary document see N94-12471 01-43)

Copyright Avail: CASI HC A02/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Within the TREES (Tropical Ecosystem Environment monitoring by Satellites) project, there is a high probability of encountering areas of terrain variations of such an extent that routine classifications of the corresponding Synthetic Aperture Radar (SAR) imagery will be severely limited. In recognition of this, a minimal number of desirable sets of information relating to the topography was identified. The generation of the data sets was shown to be clear when a digital elevation model is available, using a three dimensional simulation of sensor/target geometry to derive them; when no terrain information is available, an attempt must be made to generate the information by other means or risk a higher failure rate of the classification. A method to derive some of the data sets using SAR interferometry is outlined and the results generated using ERS-1 data taken over Sardinia (Italy) are presented. ESA

Farnborough, England.), and A. J. Sieber *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 671-677 (For primary document see N94-12471 01-43)
Copyright Avail: CASI HC A02/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Within the TREES (Tropical Ecosystem Environment monitoring by Satellites) project multitemporal ERS-1 Synthetic Aperture Radar (SAR) data of West Africa were used to investigate their information content for monitoring tropical ecosystems. Classification methodology to exploit both the tonal and textural characteristics of ERS-1 SAR imagery is described. A visual interpretation and supervised classifications were carried out for a forest/nonforest discrimination. The results are presented visually as images and as confusion matrices. It was found that the classification accuracies for the ERS-1 SAR data are in general low, but can be improved using multitemporal data and texture information. ESA

A FIRST ASSESSMENT OF THE VALUE OF ERS-1 SCATTEROMETER WINDS FOR METEOROLOGICAL STUDIES IN THE POLAR REGIONS
J. Turner and J. P. Thomas *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 701-704 (For primary document see N94-12471 01-43)
Copyright Avail: CASI HC A01/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

ERS-1 scatterometer winds for the Southern Ocean were examined in conjunction with conventional surface meteorological analyses to assess their value in investigations of the meso and synoptic scale structure of high latitude weather systems. Fast delivery surface wind vectors for Jan. to Jul. 1992 were examined. Early data showed significant problems with ambiguity removal, although later data were improved and only occasional directional errors were encountered. The resolution of the winds appeared variable with constant directions and speeds being found occasionally over large areas. Early case studies show the potential of the data with good resolution of flow in the vicinity of fronts and around isolated islands. ESA

Statistics from validations of altimeter and scatterometer data are presented. The scatterometer winds were processed from the sigma O's in house and dealiased with the help of U.K. Meteorological Office (UKMO) operational global model background winds. The altimeter data were obtained directly from the ESA fast delivery product. Winds derived from the scatterometer were assimilated into the UKMO atmospheric forecast model and preliminary results from these assimilations are presented. The derived wind fields from atmospheric assimilations were used to drive a global wave model to measure their impact on analyzed wave fields. Preliminary experiments to assimilate the altimeter wave data directly into the wave model are reported. Further work to optimize the use of these new data sources is anticipated. ESA

The first phase of a pilot project whose aim was to evaluate the quality improvement of marine meteorological forecast and analysis, using the information provided on sea state by the three instruments of the ESA ERS-1 satellite (Synthetic Aperture Radar (SAR) in wave mode, wind scatterometer, and radar altimeter) is reported. The mastery in the domains of data acquisition (fast delivery), via a server installed at the French meteorological office, and in the domain of data management and archiving (applied to the site climatology study) was given. This implied the first handling of visualization softwares, and permitted a first visual evaluation of the data. The first analysis and controls for the data quality were achieved. ESA

USE OF ERS-1 SCATTEROMETER WINDS IN CANADIAN FORECAST CENTRES c47
Patrick King *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 721-724 (For primary document see N94-12471 01-43)
Copyright Avail: CASI HC A01/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

The current and future use of ERS-1 scatterometer data at the Canadian Meteorological Centre (CMC) in Montreal and at regional forecast centers is described. Scatterometer data are received at CMC, decoded, filtered, and retransmitted as pseudo ship codes to weather forecast centers. Each office plots the data on maps which are then used in conjunction with conventional data. Forecasters record their first impressions on the supplementary chart. They then make a systematic comparison of the scatterometer data with the latest analysis done using conventional data. In the Spring of 1993 a systematic evaluation of the effect that the scatterometer data has made on analyses and forecasts will be made. A systematic comparison is being made between CMC model winds and scatterometer winds. Experiments are planned in assimilating scatterometer data into both global and regional models. ESA

ERS-1 AND ALMAZ SAR OCEAN WAVE IMAGING OVER THE GULF STREAM AND THE GRAND BANKS **c48**
David George Tilley and Robert Carl Beal *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 729-734 (For primary document see N94-12471 01-43)
Copyright Avail: CASI HC A02/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Initial assessments of both Almaz and ERS-1 image quality were compared with a similar Seasat Synthetic Aperture Radar (SAR) evaluation. ERS-1 and Almaz spectral estimates were collected nearly simultaneously and coincidentally in the Labrador Sea (Canada), and then compared with both aircraft SAR and directional buoy spectra. Similarly to Seasat, ERS-1 spectra were found to be substantially attenuated in the azimuth (along crack) direction, with typical falloff wavelengths of 250 m or more. The Almaz SAR responded well to wavelengths as short as 100 m. The SAR signal to noise response, however, was about a factor of four lower for Almaz than for ERS-1. ERS-1 imagery of the Gulf Stream was examined in four passes. Linear features in the SAR imagery were compared with satellite IR imagery, and were found to agree with the thermal fronts within 5 km. The results so far support the idea that a future wide swath scansar will be a valuable tool for monitoring large scale ocean dynamics at high resolution. ESA

REAL TIME PROCESSING WAVE SPECTRA FROM SATELLITE SAR **c48**
Ian S. F. Jones *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 735-737 Sponsored by Esso-BHP (For primary document see N94-12471 01-43)
Copyright Avail: CASI HC A01/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

A scheme under development to exploit a remote sensing technique to provide real time, deep ocean wave spectra at a significant number of points below a satellite track is reported. Real time is taken to mean within four hours of reception and will be achieved by retransmission at 1/10 the original rate (that is transmitted at 10 Mbits/sec) from a tape recorder. The processing system and computer program used are described. After a short delay the program WASP (Wave Spectral Program) produces 4 spectra per swath continuously. Synthetic Aperture Radar (SAR) signals from the ERS-1 were used in the tests to date and an intercomparison between a pass across Bass Strait (Australia) during a storm and the directional wave gauge installed on an offshore platform is presented. A number of critical elements in a 'real time' ocean wave spectra delivery system and the outstanding issues were identified. The first example used to test those components that are in place employed the ERS-1 satellite as it traversed Bass Strait. This was the occasion when there was a typical storm in progress below the satellite. The wind waves however were traveling in a nearly azimuth direction and as expected this did not produce a strong wave image. ESA

A STATISTICAL ANALYSIS OF SEA STATE SURFACE ERS-1 SAR-WAVE MODE IMAGETTES **c48**
B. Chapron, R. Garello (Ecole Nationale Superieure des Telecommunicatons, Brest, France.), and G. Engen (Forut, Tromsoe, Norway.) *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 739-742 (For primary document see N94-12471 01-43)
Copyright Avail: CASI HC A01/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

The statistical properties of ERS-1 Synthetic Aperture Radar (SAR) wave mode imagettes are presented. Acknowledging the different mechanisms affecting the imaging processes of the ocean surface with a SAR, the aim of such analysis is to extract relevant parameters to complete the traditional spectral information. The statistical properties of the images depend on the roughness of the sea, the underlying long wave system, the instrument characteristics, and the space-time variation of the surface. Following previous studies on the application of non-gaussian noise model, the use of K distribution and Gamma probability law to describe different SAR images is discussed. Based on the analysis of ERS-1 imagettes, the use of such models helps not only in the classification of the products, but also for their possible physical interpretation and link with the nonlinear ocean SAR integral transform widely used to interpret the distorted mapping commonly observed with SAR instruments. A NEW MODEL FOR SYNTHETIC APERTURE RADAR (SAR) IMAGES FROM OCEAN SCATTER **c48**
M. L. Heron and I. Amadou *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 743-745 Sponsored by DSTO, Adelaide, Australia (For primary document see N94-12471 01-43)
Copyright Avail: CASI HC A01/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

A project to produce a model which will incorporate dynamic features of the ocean surface to determine instantaneous scattering points, and calculate the complex image by conventional Kirchoff integral is introduced. In this calculation all the known effects of modulation of the short wavelengths Bragg scatterers like tilting, straining, and velocity bunching will be taken into account. The Doppler shift for each scattering facet is therefore made up from that due to the motion of the satellite plus that due to the surface dynamics. Initial calculations using this model indicate that the scattering patch size depends on look angle, wave parameters, platform, and altitude. A validation experiment was proposed using the NASA DC-8 AirSAR flying with synthetic aperture radars operating simultaneously in the X band, C band and in L band and flying along the same track at the same time and with the same look angle as ERS-1, at a site instrumented for wave directional spectra. The ERS-1 Synthetic Aperture Radar (SAR) wave mode data contain valuable global information on the full two dimensional ocean wave spectrum. This must be extracted, however, from nonlinearly distorted images. Wave spectra were derived from SAR wave mode image spectra using Hasselmann's inversion scheme based on their closed nonlinear spectral integral transform relation describing the mapping of a wave spectrum into a SAR image spectrum. The scheme uses a first guess (WAM) model wave spectrum as regularization term. The optimally fitted wave spectra yield simulated SAR image spectra in good agreement with measured SAR spectra. The wave spectra provide significant wave heights to the same accuracy as ERS-1 radar altimeter. The separation of the SAR derived wave spectra into individual wave systems using a partitoning technique showed excellent overall agreement with modeled wave spectra while demonstrating the complexity of typical wave spectra in the open ocean. Thirteen radar images acquired over the Strait of Gibraltar by the Synthetic Aperture Radar (SAR) aboard the ERS-1 satellite in the period from Jan. to Mar. 1992 were analyzed. Most of them show surface manifestations of nonlinear internal waves in the way theory predicts. In addition, the SAR images display features in the surface roughness pattern that were not known before. For the first time, internal waves propagating southward from Gibraltar across the Strait were detected. ESA

The validation of the ERS-1 Along Track Scanning Radiometer (ATSR) data is described. This microwave radiometer was designed to correct the altimeter tropospheric path for the delay due to humidity. The data quality assessment consisted of verifying the instrument calibration, then of comparing the retrieved geophysical products with available observations. The inflight calibration included control of gain stability and long term survey of internal and brightness temperature variations, as well as footprint location verification. No anomaly was detected after one year. Data validation was performed by comparing routine radiosonde measurements with the retrieved water vapors and altimeter path corrections. There is no routine measurement of cloud water content, so this retrieval cannot be simply tested. The water vapor content and altimeter tropospheric path correction retrievals were validated. ESA

An algorithm to retrieve Sea Surface Temperature (SST) based on the simulated Along Track Scanning Radiometer (ATSR) data over the Indian Ocean with the help of radiative transfer models is described. Details of the atmospheric profiles used for ATSR data simulation representing the Indian tropical conditions are given. Error estimate, advantages and disadvantages of such retrieval are discussed. It was found that observations from the ATSR and Microwave Sounder (MWS) onboard the first European Remote Sensing Satellite (ERS-1) enabled retrieval of SST within an accuracy of 0.3K because dual angle capability by ATSR accompanied by total water vapor content retrieved by MWS is expected to reduce the existing ambiguities due to atmospheric stratifications especially in tropics. ESA

Innovative methods to obtain information about the boundary layer and the interfacial layer at the Earth-atmosphere boundary, which is essential for the understanding of the energy exchange processes, are addressed. A possible method for these calculations based on the data from ERS-1 ATSR/M (Along Track Scanning Radiometer/M), scatterometer, and the NOAA Tiros Operational Vertical Sounder (TOVS) is described. The NOAA-TOVS can provide information about the vertical structures of the humidity and the temperature at coarse levels. The oblique view angles of the ERS-1 ATSR/M observations in the thermal spectral bands have capability to detect the stratifications in the boundary layer. These combined with NOAA inferences are found to provide adequate representation of the lower boundary layer. ESA

ATSR CORRELATIVE SKIN MEASUREMENTS OF SEA SURFACE TEMPERATURE **c48**
Peter Schluessel and Jens Meywerk *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 779-784 Sponsored by DFG, and BMFT (For primary document see N94-12471 01-43)
Copyright Avail: CASI HC A02/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Case studies which showed that Sea Surface Temperature (SST) as derived from Along Track Scanning Radiometer (ATSR) with different retrieval algorithms match the surface skin temperatures which were measured with a precisely calibrated radiation thermometer within few tenths of a degree are discussed. Partly cloudy ATSR data was used too and showed to be of value for SST retrievals within 0.5 to 1K accuracy. Retrieval coefficients that are designed for the use with Advanced Very High Resolution Radiometer (AVHRR) data are inadequate for the use with ATSR measurements. The cloud detection scheme of SADIST (Synthesis of ATSR Data Into Sea surface Temperature) properly rejects cloudy pixels but also cloud free measurements in areas with strong SST gradients. The colocation of nadir and forward view measurements as given from the SADIST processing needs a further improvement for a better match up. A further validation of ATSR derived sea surface temperatures is essential in order to get statistically significant conclusions about the accuracy of the derived products. ESA

VALIDATION OF ATSR-1 USING AIRCRAFT RADIOMETER MEASUREMENTS OVER THE SOUTH ATLANTIC
A. H. Smith and R. W. Saunders *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 785-790 (For primary document see N94-12471 01-43)
Copyright Avail: CASI HC A02/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

The first Along Track Scanning Radiometer (ATSR) tropical experiment, carried out in Nov. 1991 to validate the ATSR measurements of Sea Surface Temperature (SST) in the tropics is reported. A multichannel radiometer which had channels spectrally matched to those at 11 and 12 micrometers on the ATSR was flown around the tropics (8 deg South, 14 deg West) on a C130 aircraft and used to make radiance and brightness temperature measurements at a number of different altitudes. An attempt to quantify the absorption/emission effect of any stratospheric aerosol due to the eruption of Mount Pinatubo in Jun. 1991 was made. ATSR sea surface temperature retrievals (using both nadir and forward instrument views) were compared with low level measurements of radiative sea surface temperature. Brightness temperature profiles of the atmosphere were obtained for comparison with those obtained from the Rutherford Appleton Laboratory radiative transfer model which was used to generate the ATSR SST retrieval coefficients. ESA

The Along Track Scanning Radiometer (ATSR) Near Real Time (NRT) demonstration project, which was established to address the needs of meteorological centers for Fast Delivery (FD) data, is reported. The ATSR NRT products consist of 0.5 deg. by 0.5 deg. Average Sea Surface Temperatures (ASST) plus ancillary data. The aim of the project was to show that the data processing and transmission system devised can provide data, of high quality and in near real time, to an end user. If this can be achieved then it is hoped that the system will eventually be adopted by ESA as part of the ERS-1 FD service. The NRT ASST's were assessed by comparison with coincident SST's derived from the U.K. meteorological office operational global SST analysis and with collocated, high quality drifting buoy observations. The evaluation was further subdivided into day and nighttime observations and those resulting from the use of single and dual view data because different algorithms are used for the SST retrieval under these conditions. It was found that a bias of around -0.4 K exists. This can largely be attributed to the genuine difference between the temperature of the ocean's radiative skin, as measured by ATSR, and the sub-surface bulk temperature measured by buoy sensors. ESA

A campaign made between Oct. 1991 and May 1992 to make in situ Sea Surface Temperature (SST) measurements to validate the Along Track Scanning Radiometer (ATSR) SST product is reported. The campaign was carried out on a ship as it sailed from the U.K. to Antarctica and back. The ship carried an infrared radiometer, a temperature sensor trailed from the side, and a hull thermistor. The results showed that the present ATSR SST product gives results cooler than the in situ measurements. In the tropics the difference was less than or equal to 1K except in the one case where the forward view was used in the retrieval, when agreement was within 0.1K. ESA

PRELIMINARY VALIDATION OF ATSR SEA SURFACE TEMPERATURES NEAR THE FAEROES c48

T. N. Forrester, T. H. Guymer, and P. G. Challenor *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 807-811 (For primary document see N94-12471 01-43)

Copyright Avail: CASI HC A01/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Measurements of sea surface temperature made with a thermosalinograph on a cruise near the Faeroes (Norwegian sea) were compared with those derived from the Along Track Scanning Radiometer (ATSR) on ERS-1. Qualitatively, the temperature fields are very similar and show that the area was under the influence of the Iceland-Faeroes Front. Although the presence of significant horizontal gradients and of appreciable amounts of cloud complicated the analysis, it was demonstrated that the accuracy of the ERS-1 temperatures is within their design specification of 0.5K. The ERS-1 values are a few tenths of a Kelvin colder than the in situ data, this is consistent with the skin effect. ESA

Copyright Avail: CASI HC A01/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

On 10 and 13 Nov. 1991, an experiment to detect artificial oil pollution and ocean waves was performed using the C band Synthetic Aperture Radar (SAR) of ERS-1. An artificial oil slick was made by spilling oleyl alcohol from a small vessel in the Pacific ocean about 100 km off the coast of Omaezaki, Shizuoka prefecture (Japan). Sea truth data were gathered from a research vessel and from another small vessel. Synchronous observation by X band, VV polarization airborne real aperture Side Looking Airborne Radar (SLAR) was made together with the observation by SAR. In the 10 Nov. 1991 SAR image, the artificial oil spill, which appeared to be dark because of capillary wave action, was clear. The decrement of the scattering cross section was about 2.5 dB at the maximum. ESA

SHIP TRAFFIC MONITORING USING THE ERS-1 SAR

Terje Wahl, Knut Eldhuset, and Aage Skoeelv *In* ESA, Proceedings of 1st ERS-1 Symposium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 823-828 Sponsored in part by Norwegian Space Center (For primary document see N94-12471 01-43)

Copyright Avail: CASI HC A02/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

A fast processing and distribution chain for ERS-1 Synthetic Aperture Radar (SAR) images was developed in Norway. Large quantities of ERS-1 images were used to assess the ship detection and wake imaging capability of ERS-1. Also, there is an ongoing campaign for detection of oil spill from ships along the Norwegian coast. Automatic detection and analysis of ships and ship wakes using the 30 m resolution SAR fast delivery product was demonstrated. For oil spill detection, 100 m resolution images of high radiometric quality are used. Ships above 120 m in length are generally seen in ERS-1 images under most weather conditions. Ships smaller than 100 m may sometimes become practically invisible in the SAR images because of the strong backscatter from the sea surface at some wind speeds. The main cause of this detection problem is the rather steep incidence angle of ERS-1. Ship wake signatures in ERS-1 images are very similar to those in Seasat images. The most frequent wake feature is the dark turbulent wake. Several confirmed observations of oil slicks have been reported. At low wind speed, natural surface slicks may in some cases be classified as oil slicks. ESA

The aim of this project is to develop and demonstrate a system for early oil spill detection using satellite based Synthetic Aperture Radar (SAR). During the Dedicated Oil Spill Experiment in Aug. 1991 (DOSE-91), three slicks, each 20 tons of stabilized crude oil, were released in phase with the passages of the ERS-1 satellite. Sea truthing, oil slick tracking using drifting buoys, and aircraft surveillance using various remote sensing techniques to compare and verify satellite observations were performed. The observations gathered during the experiment are presented with emphasis on the SAR imagery of oil slicks under certain environmental conditions. Image enhancement techniques used to process the imagery are also discussed. ESA

A few Synthetic Aperture Radar (SAR) scenes, acquired in Apr. (roll tilt mode, 35 deg. incidence angle) and May 1992 (normal mode, 23 deg. incidence) and available since early Oct. 1992 were evaluated in the following principal thematic applications: morphotectonics, coastal geomorphology, mapping of surficial deposits, and hydrology. The first analysis showed that SAR ERS-1 imagery can contribute, in an original way, to the applications mentioned above, in inland, where the main structural lineaments and lithological units can be easily detected under heavy canopy, as well as in coastal zones where the image resolution is well adapted to the study of erosion and progradation zones, characteristic to the area, and to estimate flood plains during rain periods (during which 'optical' images can not be used). A study of the correlation between meteomarine conditions and the sediment on several beaches in the Mediterranean and in the North Sea is reported. The textural and morphological characteristics of a beach test which resulted from several in situ measurement campaigns are presented. The data processing and production of ERS-1 Synthetic Aperture Radar (SAR) images are described. Correlations with wavelength, swell height, and width are presented. ESA

The mapping of sea bottom topography with ERS-1 C band Synthetic Aperture Radar (SAR) was investigated giving particular attention to the range of hydrometeo parameters under which bottom topography can be observed as well as the optimum parameters. Practical application for monitoring sand waves was considered. A number of ERS-1 C band SAR images of a test area off the Dutch coast were collected. Hydrometeo data were measured on a fixed platform close to the test area. The surface current is obtained from a quasi-three dimensional flow model. Images showing bottom topography were compared with a detailed bathymetric map of the test area and with predictions from state of the art models of the imaging mechanism. ESA

A project area was selected in the northern part of the Dutch Waddensea between the island of Vlieland and the town of Harlingen, to investigate the usefulness of ERS-1 radar imaging data for mapping and monitoring. With the radar data, use will be made of the fundamental properties of this area; the dynamics of the tidal cycle and the waterlines which are examples of these properties. A mapping procedure was established on the basis of existing LANDSAT data, consisting of landwater classification, filtering procedures for smoothing the waterline, construction of water surface models at time of data acquisition, defining height elevations along the waterline, and error evaluation on basis of a ground truth mapping digital elevation model. For satellite radar observations a similar procedure will be followed. Before the radar waterline method may be applied, a fundamental question as to whether or not the water-land boundaries on ERS-1 C band radar are clearly mappable under different weather and seastate conditions has to be answered. Meteo and sea state observations were obtained during ERS-1 data acquisition, which may give an answer after the radar data have been processed in future. ESA

A preliminary account of studies linking offshore field work, carried out since 1968 and continuing at present, with Synthetic Aperture Radar (SAR) images obtained in 1978 (Seasat) and with ERS-1, which are being used to determine the value of the system for shallow water geological mapping is given. In addition, changes in the morphology of large mobile sand bedforms are being monitored in order to aid in decisions affecting coastal environmental and protection management. This in particular concerns monitoring changes to coastal sedimentological pathways and 'cells.' ESA

Initial analyses of ERS-1 Synthetic Aperture Radar (SAR) images of geomorphic features around Alaska are summarized. Tha aim of this analysis was to determine the utility of such images in monitoring environmental conditions and processes important for managing water resources. Patterns on SAR images were compared to those on LANDSAT images, and data from ground penetrating radar and field observations were used to interpret the SAR images. These comparisons showed that the ERS-1 SAR can do the following: locate unfrozen water beneath river and lake ice on the Sagavanirktok River floodplain; determine the general ice, snow, and sediment conditions along the Matanuska Glacier; show general nearshore ice conditions and coastal geomorphology along Alaska's north shore; and delineate coastal wetlands vegetation along Knik Arm. These results suggest that the ERS-1 SAR imagery will be a valuable source of environmental data for addressing water supply in cold regions, for glacial monitoring, for coastal navigation, and for assessing wetland conditions. An ERS-1 project to evaluate the ERS-1 microwave sensors capability in the study of oceanic fronts which aimed at observing the location and evolution of surface density structures in the western Mediterranean by using Synthetic Aperture Radar (SAR) imagery and altimetry is addressed. The mesoscale dynamics related to salinity gradients play a major role in delineating the regional general circulation. Mesoscale eddies were observed in ERS-1 SAR images in Nov. 1991, and a comparison of in situ data to SAR scenes in a shelf/slope area of the north west Mediterranean was made. Complex structures were observed to be related to the influence of a submarine canyon on an alongslope flow. ESA

The determination, with the best possible accuracy, of the orbit of an oceanographic satellite like ERS-1 with an onboard altimeter is discussed. The tracking system is the laser network. The radial component of the position vector of the satellite is of particular importance. In the Mediterranean area for ERS-1 an accuracy better than 10 cm can be obtained, and in some cases, for which the geometry of the tracking network is favorable, this accuracy can be of the order of 5 cm. ESA

TOPOGRAPHY OF THE WESTERN MEDITERRANEAN FROM THE ERS-1 ALTIMETER

T. H. Guymer and R. T. Tokmakian *In* ESA, Proceedings of 1st ERS-1 Sympsoium on Space at the Service of Our Environment, Volume 2 Mar. 1993 p 893-898 (For primary document see N94-12471 01-43)

Copyright Avail: CASI HC A02/MF A03; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

A preliminary analysis of ERS-1 altimeter height data in the western Mediterranean was conducted using all available off line data in the Algero-Provencale Basin. Sea level variability is shown to be 5 cm or less and it is suggested, in line with previous work, that the region is suitable for calibration of the altimeter height measurements. Further examination of the height residuals, however, showed that they may contain oceanographic information. In particular, features were found in the southern portion of the Basin which are consistent with the migration of mesoscale eddies from the Algerian Current, as is known to happen. The observed features cannot be explained by errors in the altimeter corrections. ESA

DEPARTMENT OF ENERGY SOLAR PROCESS HEAT PROGRAM: FY 1991 SOLAR PROCESS HEAT PREFEASIBILITY STUDIES ACTIVITY

R. Hewett Nov. 1992 4 p Presented at the SOLAR 1993 ASME American Solar Energy Society Joint Solar Energy Conference, Washington, DC, 22-28 Apr. 1993

(Contract DE-AC02-83CH-10093)

(DE93-010010; NREL/TP-432-5068; CONF-930435-8) Avail: CASI HC A01/MF A01

During fiscal year (FY) 1991, the US Department of Energy (DOE) Solar Process Heat Program implemented a Solar Process Heat Prefeasibility Studies activity. For Program purposes, a prefeasibility study is an engineering assessment that investigates the technical and economic feasibility of a solar system for a specific application for a specific end-user. The study includes an assessment of institutional issues (e.g., financing, availability of insurance, etc.) that impact the feasibility of the proposed solar project. Solar process heat technology covers solar thermal energy systems (utilizing flat plate or concentrating solar collectors) for water heating, water preheating, cooling/refrigeration, steam generation, ventilation air heating/preheating, etc., for applications in industry, commerce, and government. The studies are selected for funding through a competitive solicitation. For FY-91, six projects were selected for funding. As of 31 Aug. 1992, three teams had completed their studies. This paper describes the prefeasibility studies activity, presents the results from the study performed by United Solar Technologies, and summarizes the conclusions from the studies that have been completed to date and their implications for the Solar Process Heat Program. JAPAN'S SUNSHINE PROJECT

Jul. 1992 528 p

(DE93-767980; ETDE/JP-mf-93767980) Avail: CASI HC A23/MF A04

The 1991 results of the Sunshine Project/solar energy research and development are described. As for solar energy utilization, R and D are made on types of advanced, high-efficiency, and amorphous solar cells. Photovoltaic hydrogen production and CO2 fixation are also studied. For commercialization of the photovoltaic power generation system, technologies for thin substrate solar cells and tandem solar cells are studied. Research is made on integration of amorphous solar cells for electric power use, layer formation using new raw material gas, and production technology for high reliability and high quality. Studies are made on a new production method for ultra-high efficiency solar cells and compound semiconductor solar cells. Evaluation technology and peripheral technology for the photovoltaic power generation system are studied. As for the photovoltaic power generation utilization system, a photovoltaic-wind power generation hybrid system and a photovoltaic-thermal hybrid system are studied. The analysis/evaluation method is studied for commercialization of the photovoltaic power generation system. Concerning solar heat utilization, research is conducted on equipment, materials, elementary technology for commercialization of the industrial use solar system, solar heat refrigeration, the passive solar system, etc. International cooperation is also referred to. US AREAL WIND RESOURCE ASSESSMENT

M. N. Schwartz and D. L. Elliott Mar. 1993 5 p Presented at the Alternate Fuels and the Environment Symposium, Denver, CO, 28 Mar. - 2 Apr. 1993

(Contract DE-AC06-76RL-01830)

(DE93-011905; PNL-SA-21606; CONF-9303133-1) Avail: CASI HC A01/MF A01

Estimates of the electricity that could potentially be generated by wind power and of the land area available for wind energy development have been calculated for the contiguous United States, in support of the US Department of Energy's National Energy Strategy. These estimates were based on the wind resource data published in a national resource atlas. Estimates of the wind resource in this atlas are expressed in wind power classes ranging from class 1 to class 7, with each class representing a range of mean wind power density or equivalent mean speed at specified heights above the ground. Areas designated class 4 or greater are suitable for most wind turbine applications. Power class 3 areas are suitable for wind energy development using tall (50m hub height) turbines. Class 2 areas are marginal, and class 1 areas are unsuitable for wind energy development. A map of the areal (percentage of land area) distribution of the wind resource digitized in grid cells (1/4 deg latitude by 1/3 deg longitude) shows that exposed areas with moderate to high wind resource (class 3 and greater) are dispersed throughout much of the contiguous United States. DYNAMICS OF CHARGE-TRANSFER EXCITED STATES RELEVANT TO PHOTOCHEMICAL ENERGY CONVERSION
E. C. Lim 1993 5 p
(Contract DE-FG02-89ER-14024)
(DE93-013981; DOE/ER-14024/4) Avail: CASI HC A01/MF A01

A systematic study of intramolecular photoassociation and photoinduced charge transfer (CT) was initiated in bichromophoric systems of M-X-M, where two identical aromatic hydrocarbons, M, are joined by X = CH2, O, NH, etc. Dinaphthylamines, dinaphthylethers, and dinaphthylmethanes in nonpolar solvents form triplet excimers, following intersystem crossing of singlets to the triplet manifold; in polar solvents, the molecule forms an intramolecular CT state. The interchromophore interaction study was extended to N-phenyl-2-naphthylamine. The lowest excited singlet states of the dinaphthylamines were studied by semiempirical quantum chemical methods. Exciplex formation was studied in excited states of jet-cooled van der Waals complexes, such as fluorene/substituted benzenes and 1-cyanonaphthalene-aliphatic amines. DOE

FATIGUE LIFE PREDICTION FOR WIND TURBINES: A CASE STUDY ON LOADING SPECTRA AND PARAMETER SENSITIVITY
H. J. Sutherland, P. S. Veers, and T. D. Ashwill 1992 39 p Presented at the 5th ASTM Symposium on Composite Materials: Fatigue and Fracture, Atlanta, GA, 4-6 May 1993
(Contract DE-AC04-76DP-00789)
(DE93-011597; SAND-92-0501C; CONF-930532-2) Avail: CASI HC A03/MF A01

Wind turbines are fatigue-critical machines used to produce electrical energy from the wind. These rotating machines are subjected to environmental loadings that are highly irregular in nature. Historical examples of fatigue problems in both research and commercial wind turbine development are presented. Some example data on wind turbine environments, loadings and material properties are also shown. Before a description of how the authors have chosen to attack the cumulative damage assessment, questions are presented for the reader's reflection. The solution technique used by the authors is then presented, followed by a case study applying the procedures to an actual wind turbine blade joint. The wind turbine is the 34-meter diameter vertical axis wind turbine (VAWT) erected by Sandia National Laboratories near Bushland, Texas. The case study examines parameter sensitivities for realistic uncertainties in inputs defining the turbine environment, stress response and material properties. The fatigue lifetimes are calculated using a fatigue analysis program, called LIFE2, which was developed at Sandia. The LIFE2 code, described in some detail in an appendix, is a PC-based, menu-driven package that leads the user through the steps required to characterize the loading and material properties, then uses Miner's rule or a linear crack propagation rule to numerically calculate the time to failure. Only S-n based cumulative damage applications are illustrated here. The LIFE2 code is available to educational institutions for use as a case study in describing complicated loading histories and for use by students in examining, hands on, parameter sensitivity of fatigue life analysis. THIN FILM PREPARATION AND INTERFACIAL REACTION STUDY OF SOLID OXIDE FUEL CELL MATERIALS
Chieh-Cheng Chen 1992 148 p
Avail: Univ. Microfilms Order No. DA9311023

Solid oxide fuel cells (SOFC's) operate at 1000 C and their components are processed at even higher temperatures. It is generally desirable to reduce the operating and processing temperatures of SOFC's to make them competitive with other types of fuel cells and to avoid the interactions and interdiffusion between cell components. This can be achieved by either developing a technology to produce thin film electrolytes, or by developing new electrolyte and electrode materials with reduced interaction, lower interfacial resistance. The synthesis and characterization of (Ce-O2)0.8(Sm01.5)0.2 thin films from polymeric precursors is discussed. The reaction mechanism of the precursors and important parameters for making dense, crack-free films were investigated. The cathode/electrolyte interactions and their expected impact on SOFC performance are addressed. The cathode characteristics and cathode/electrolyte interaction of various perovskites are studied. The impact of interfacial reactions on cell performance is investigated. The electrode characteristics of dense La0.6Sr0.4Co0.2Fe0.8O3 (LSCF) thin film produced by polymeric precursors are presented. The electrode resistance and characteristics of the electrode (dense)/electrolyte interface are studied. The effect of reactions and interdiffusion on interfacial resistance are discussed. A potential method for making dense ZrO2 films at relatively low temperatures by plasma-enhanced chemical vapor deposition is presented. The deposition parameters and characterization of ZrO2 film are reported. Dissert. Abstr.

MEASUREMENT AND MODELING OF THE STABILITY OF HYDROGENATED AMORPHOUS SILICON SOLAR CELLS AND FILMS AFTER INTENSE ILLUMINATION Ph.D. Thesis
Xiao-Rui Li 1993 117 p
Avail: Univ. Microfilms Order No. DA9311203

Hydrogenated amorphous silicon p-i-n solar cells were aged under high-intensity illumination at 50 to approximately 60 C, well into saturation of their conversion efficiency. The cell characteristics were measured at intervals, and also modeled numerically with the model for Analysis of Microelectronic and Photonic Structures (AMPS). The light-induced degradation in the isolated i-layer films, grown under identical conditions to the cells, were also studied using the Constant Photocurrent Method. The

CPM-measured defect density was fitted to strenched exponential form, which become input parameters for the modeling. The model results agree with the experimental data very well, suggesting that the light-induced defect density in the bulk i-layer is primarily responsible for the cell degradation under light. Model results also suggested that a new degradation mechanism - the p/i interfacial defects might exist, contributing to the cell degradation as well. The defect density at the p/i interface rise with illumination time. However, this needs to be verified experimentally. The modeling results predict that the cells with thickness of 200nm have the best long term stability. The a-Si:H material with the saturated defect density of approximately 10(exp 16) cm(sup -3) is the target for improving stability of solar cells. The material with this saturated defect density will give a cell with stabilized conversion efficiency of 90 percent of initial value. This shows that growing stable a-Si:H films with low defects is the key for a stable a-Si:H p-i-n solar cell with high conversion efficiency.

POLYMER ELECTROLYTE FUEL CELLS: POTENTIAL TRANSPORTATION AND STATIONARY APPLICATIONS
S. Gottesfeld 1993 13 p Presented at the EPRI/GRI Fuel Cell Review Meeting, New Orleans, LA, 12-14 Apr. 1993
(Contract W-7405-eng-36)
(DE93-010734; LA-UR-93-1018; CONF-9304108-1) Avail: CASI HC A03/MF A01

The application of the polymer electrolyte fuel cell (PEFC) as a primary power source in electric vehicles has received increasing attention during the last few years. This increased attention is the result of a combination of significant technical advances in this fuel cell technology and the initiation of some projects for the demonstration of a complete, PEFC-based power system in a bus or in a passenger car. Such demonstration projects reflect an increase in industry's faith in the potential of this technology for transportation applications, or, at least, in the need for a detailed evaluation of this potential. Nevertheless, large scale transportation applications of PEFC's require a continued concerted effort of research on catalysis, materials, and components, combined with the engineering efforts addressing the complete power system. This is required to achieve a cost effective, highly performing PEFC stack and power system. A related set of technical and cost challenges arises in the context of potential applications of PEFC's for stationary power applications; although, there are clearly some differences in their nature, particularly, having to do with the different types of fuels to be employed for each of these applications. We describe in this contribution some recent results of work performed by the Core Research PEFC Program at Los Alamos National Laboratory, which has addressed materials, components, and single cell testing of PEFC's. Also included are some recent observations and some insights regarding the potential of this fuel cell technology for stationary power generation. DOE

(DE93-009565; ORNL/FTR-4479) Avail: CASI HC A03/MF A01 (US Sales Only)

The author attended the 35th Annual Congress of the Mexican Physics Society. A presentation at a roundtable on environmental contamination focused on groundwater and soil contamination problems at Department of Energy facilities. Another invited presentation to the general public and staff of the University of Puebla was about radon in indoor environments and the associated risks of lung cancer. Discussions were held with National Autonomous University of Mexico (UNAM) staff on aspects of environmental contamination monitoring that are of mutual concern. Plans were made to develop joint proposals under the new cooperative research agreement between UNAM and Oak Ridge National Laboratory (ORNL). Arrangements were also made for two UNAM staff members to work at ORNL in 1993.

TOXIC CHEMICAL RELEASE INVENTORY REPORTING FORM R AND INSTRUCTIONS. REVISED 1992 VERSION. SECTION 313 OF THE EMERGENCY PLANNING AND COMMUNITY RIGHT-TO-KNOW ACT
Jan. 1993 121 p See also 1988 version, PB89-164248 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-194140; EPA/745/K-93/001) Avail: Issuing Activity (National Technical Information Service (NTIS))

Reporting is required to provide the public with information on the releases of listed toxic chemicals in their communities and to provide EPA with release information to assist the Agency in determining the need for future regulations. Facilities must report the quantities of both routine and accidental releases of listed toxic chemicals, as well as the maximum amount of the listed toxic chemical on-site during the calendar year and the amount contained in wastes transferred off-site. These instructions supplement and elaborate on the requirements in the reporting rule (40 CFR Part 372). Together with the reporting rule, they constitute the reporting requirements. All references in these instructions are to sections in the reporting rule unless otherwise indicated. NTIS

ENVIRONMENTAL PROTECTION AGENCY'S LIFE CYCLE METHODOLOGY: GUIDELINES FOR USE IN DEVELOPMENT OF PACKAGING

Mary Ann Curran 1992 13 p See also PB93-194207 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(PB93-194199; EPA/600/A-93/112) Avail: CASI HC A03

Approaches to reducing the environmental effects of products and processes have moved steadily upstream over the years from end-of-pipe controls to source reduction and recycling of hazardous waste, and more recently, toward multimedia pollution prevention. Life Cycle Assessment (LCA) continues the trend of expanding the authors view and approach to environmental protection. An informal review of the open literature found 29 references to product life cycle studies, 17 of which are related to packaging materials or packaging systems. Beverage containers (cans, bottles, and cartons) are the focus of ten of these studies. These packaging-related studies are provided in the bibliography at the end of the paper. The paper includes discussion of the history of LCA's SETAC's involvement in LCA, the EPA's guidance on life cycle inventory methodology, life cycle design, and the future of LCA. NTIS

IMMEDIATE RESPONSE TO FREE PRODUCT DISCOVERY Remedial Action Tech Data Sheet

Nov. 1992 13 p

(PB93-182970; NEESA-20.2-051.4) Avail: CASI HC A03/MF A01

Underground storage of petroleum products such as gasoline, diesel oil, fuel oil, and aviation fuel can be a significant source of contamination of ground water and soil. Estimates by the Environmental Protection Agency (EPA) indicate that nearly 25% of all steel underground storage tanks (UST) are leaking. The need to initiate remedial measures as soon as leaking is detected is of paramount importance. For any migrating fuel plume problem, the first priority must be to gain control of the migrating product to prevent further soil and ground water contamination. Proper immediate response can significantly reduce the ultimate cleanup cost, increase the efficiency of the cleanup, and mitigate further environmental damage. NTIS

USER'S MANUAL FOR THE PLUME VISIBILITY MODEL PLUVUE 2 (REVISED) Final Report

Oct. 1992 108 p See also PB84-158302 Sponsored by EPA, Research Triangle Park, NC

(Contract EPA-68-D9-0067)

(PB93-188233; EPA/454/B-92/008) Avail: CASI HC A06/MF A02

The document provides a description for the restructured and revised version of the Plume Visibility Model (PLUVUE 2). The model was restructured in order to improve the user interface and computing requirements and revised to remove several errors in the original code. The objective of the PLUVUE 2 model is to calculate visual range reduction and atmospheric discoloration caused by plumes consisting of primary particles, nitrogen oxides, and sulfur oxides emitted by a single emission source. NUMERICAL SIMULATIONS ON THE REDISTRIBUTION OF ATMOSPHERIC TRACE CHEMICALS THROUGH CLOUD PROCESSES Ph.D. Thesis

Jen-Ping Chen 1992 360 p

Avail: Univ. Microfilms Order No. DA9311607

The redistribution of atmospheric trace substances through cloud processes is investigated using a detailed microphysical and chemical cloud model. A multi-component categorization scheme is used in the model to group cloud particles into different bins according to their various properties. Cloud drops are categorized in both their water mass and solute mass components. An extra 'shape' component is included in the ice-phase particle framework to describe the distribution of ice-phase particles. Special efforts are paid to develop the theory and parameterization for the change of the growth habits for ice particles. In dealing with a model that inevitably has a large dimension, a hybrid bin-method is applied so that it can maintain the conservation of all properties and, at the same time, perform fast and accurate calculations for transferring various properties between categories in the multi-component systems. With a minimum of parameterization, this model is capable of simulating detailed microphysical and chemical processes that occurred during cloud and precipitation formations. Using the multi-component model, it is shown that the drop number concentration is a function of both the water mass and the solute mass in the drops, a phenomenon that cannot be resolved by conventional cloud models. Applying a full set of liquid- and ice-phase microphysics, it is also shown that the number concentration of ice particles is indirectly controlled by the number concentration of cloud condensation nuclei. Bulk water models that can not treat the in-cloud supersaturation are not able to properly simulate such processes. The concept of the relative removal efficiency was introduced and tested in a simple particle model in the earlier stage of the study. An extended test on the relative removal efficiencies was done by simulating a wintertime, orographic cloud in a two-dimensional, steady-state model. Satisfactory results for both the microphysical and chemical behavior of the cloud are produced in the simulation. It is shown that the redistribution of atmospheric trace substances is controlled by their microphysical pathways. Dissert. Abstr.

EXTENDED ECOSYSTEM SIGNATURES WITH APPLICATION TO Eos SYNERGISM REQUIREMENTS Final Report

Fawwaz T. Ulaby, M. Craig Dobson, and Kamal Sarabandi Jul. 1993 24 p
(Grant NAGw-1101)
(NASA-CR-193398; NAS 1.26:193398; UMICH-024557-1-F) Avail: CASI HC A03/MF A01

The primary objective is to define the advantages of synergistically combining optical and microwave remote sensing measurements for the determination of biophysical properties important in ecosystem modeling. This objective was approached in a stepwise fashion starting with ground-based observations of controlled agricultural and orchard canopies and progressing to airborne observations of more natural forest ecosystems. This observational program is complemented by a parallel effort to model the visible reflectance and microwave scattering properties of composite vegetation canopies. The goals of the modeling studies are to verify our basic understanding of the sensor-scene interaction physics and to provide the basis for development of inverse models optimized for retrieval of key biophysical properties. These retrieval algorithms can then be used to simulate the expected performance of various aspects of Eos including the need for simultaneous SAR and HIRIS observations or justification for other (non-synchronous) relative timing constraints and the frequency, polarization, and angle of incidence requirements for accurate biophysical parameter extractions. This program completed a very successful series of truck-mounted experiments, made remarkable progress in development and validation of optical reflectance and microwave scattering models for vegetation, extended the scattering models to accommodate discontinuous and periodic canopies, developed inversion approaches for surface and canopy properties, and disseminated these results widely through symposia and journal publications. In addition, the third generation of the computer code for the microwave scattering models was provided to a number of other US, Canadian, Australian, and European investigators who are currently presenting and publishing results using the MIMICS research code.

METHODOLOGIES FOR ESTIMATING AIR EMISSIONS FROM THREE NON-TRADITIONAL SOURCE CATEGORIES: OIL SPILLS, PETROLEUM VESSEL LOADING AND UNLOADING, AND COOLING TOWERS Final Report, Oct. 1991 - Mar. 1993

W. Ramadan, S. Sleva, K. Dufner, S. Snow, and S. L. Kersteter Apr. 1993 119 p Sponsored by EPA, Research Triangle Park, NC Prepared in cooperation with Southern Research Inst., Durham, NC, and TRC Environmental Corp., Chapel Hill, NC
(Contract EPA-68-D9-0173)
(PB93-181592; EPA/600/R-93/063) Avail: CASI HC A06/MF A02

The report discusses part of EPA's program to identify and characterize emissions sources not currently accounted for by either the existing Aerometric Information Retrieval System (AIRS) or State Implementation Plan (SIP) area source methodologies and to develop appropriate emissions estimation methodologies and emission factors for a group of these source categories. Based on the results of the identification and characterization portions of this research, three source categories were selected for methodology and emission factor development: oil spills, petroleum vessel loading and unloading, and cooling towers. The report describes the category selection process and presents emissions estimation methodologies and emission factor data for the selected source categories. The discussions for each category include general background information, emissions generation activities, pollutants emitted, sources of activity and pollutant data, emissions estimation methodologies and data issues. The information used in these discussions was derived from various sources including available literature, industrial and trade association publications and contracts, experts on the category and activity, and knowledgeable federal and state personnel. CATALYTIC OXIDATION OF ORGANICS IN VAPOR STREAMS AT REMEDIATION SITES Remedial Action Tech Data Sheet

Jan. 1993 10 p
(PB93-182962; NEESA-20.2-051.5) Avail: CASI HC A02/MF A01

Leaks from underground fuel storage tanks and associated piping have resulted in contamination of soil and ground water. Navy-wide, more than 350 sites are in need of remediation to remove fuel contamination from soil and ground water. These sites are located at about 80 different Navy activities (including Marine Corps installations). As a result of remedial activities to clean these contaminated soils and ground water, contaminated air streams are often generated. Available alternatives for the treatment of these air streams include carbon adsorption and incineration. The Tech Data Sheet describes catalytic oxidation, a third alternative that has the potential to be effective at a lower cost. NTIS

STUDY OF THE ATMOSPHERIC CHEMISTRY OF RADON PROGENY IN LABORATORY AND REAL INDOOR ATMOSPHERES

P. K. Hopke Jul. 1992 12 p
(Contract DE-FG02-90ER-61029)
(DE93-012236; DOE/ER-61029/13) Avail: CASI HC A03/MF A01

This report describes studies on the chemical and physical behavior of the Po-218 atom immediately following its formation by the alpha decay of radon. Because small changes in size for activity in the sub-10 nm size range result in large changes in the delivered dose per unit exposure, this behavior must be understood if the exposure to radon progeny and its dose to the cells in the respiratory tract are to be fully assessed. The specific tasks of the controlled laboratory studies are to determine the formation rates of (center dot)OH radicals formed by the radiolysis of air following radon decay, to examine the formation of particles by the radiolytic oxidation of substances like SO2 ethylene, and H2S to lower vapor pressure compounds and determine the role of gas phase additives such as H2O and NH3 in determining the particle size, to measure the rate of ion-induced nucleation using a thermal diffusion cloud chamber, and to measure the neutralization rate of Po-218(x)(+) in O2 at low radon concentrations.

Tasks of the exposure studies in occupied indoor spaces are to initiate measurements of the activity size distributions in actual homes with occupants present so that the variability of the indoor activity size distributions can be assessed with respect to indoor aerosol sources and general lifestyle variations of the occupants, to initiate a prospective study of the utility of measurement of deposited Pb-210 embedded in glass surfaces as a measure of the long-term, integrated exposure of the population to radon, and to develop the methodology to determine the hygroscopicity of the indoor aerosol so that the changes in deposition efficiency of the radioactive indoor aerosol with hygroscopic growth in the respiratory tract can be assessed. ENERGY FLOW IN AN ARCTIC AQUATIC ECOSYSTEM
D. M. Schell 1993 8 p
(Contract DE-FG06-84ER-60265)
(DE93-013178; DOE/ER-60265/T1) Avail: CASI HC A02/MF A01

This project has been using natural isotope abundances to trace major pathways of energy flow to consumers in Imnavait Creek and the tundra ecosystem of the R4D watershed with comparative work in the coastal tundra. We are processing samples collected at the R4D intensive site over the past three years and are comparing these data with similar samples collected from the coastal plain. Our approach is as follows: to determine if carbon is accumulating in upland and coastal tundra; to determine the role of eroded peat carbon in the aquatic ecosystem; and to determine the distribution of carbon and nitrogen isotopes in the tundra-pond ecosystem to establish the feasibility of using natural differences as tracers. COPROCESSING OF FOSSIL FUELS AND BIOMASS FOR CO2 EMISSION REDUCTION IN THE TRANSPORTATION SECTOR Report, Apr. 1991 - Jul. 1992
Meyer Steinberg, Yuan-Ji Dong (Hydrocarb Corp., New York, NY.), and Robert H. Borgwardt (Environmental Protection Agency, Research Triangle Park, NC.) 1993 10 p Presented at the IEA Carbon Dioxide Disposal Symposium, Oxford, England, 29-31 Mar. 1993
(Contract EPA-IAG-DW-89934598)
(PB93-194165; EPA/600/A-93/109) Avail: CASI HC A02/MF A01

The paper discusses an evaluation of the Hydrocarb process for conversion of carbonaceous raw material to clean carbon and methanol products. As fuel, methanol and carbon can be used economically, either independently or in slurry form, in efficient heat engines (turbines and internal combustion engines) for both mobile and stationary single and combined cycle power plants. When considering carbon dioxide (CO2) emission control in the utilization of fossil fuels, the coprocessing of those fossil fuels with biomass (which may include wood, municipal solid waste, and sewage sludge) is a viable mitigation approach. By coprocessing both types of feedstock to produce methanol and carbon, while sequestering all or part of the carbon, a significant net CO2 reduction is achieved if the methanol is substituted for petroleum fuels in the transportation sector. Biomass removes CO2 from the atmosphere by photosynthesis and is thus a prime feedstock for mitigation of CO2 emission from mobile sources. Since the availability of biomass will, in most cases, determine the amount of petroleum that can be displaced, it is essential to obtain maximum yield of fuel in the conversion process. NTIS

DATA MANAGEMENT STRATEGY FOR THE TAMPA BAY NATIONAL ESTUARY PROGRAM: RECOMMENDATIONS AND IMPLEMENTATION PLAN Final Technical Report
Sara Cairns Aug. 1992 200 p
(Contract T-91-11)
(PB93-191633; TBNEP-08-92) Avail: CASI HC A09/MF A03

One goal of the Tampa Bay National Estuary Program (TBNEP) is to identify and develop the plans for a data management system that meets the needs of potential users who can benefit from improved access to information that is pertinent to resource management. As part of the project, the needs and goals of data users in the Tampa Bay area were investigated by means of a survey, followed by a workshop at which participants discussed how the DMS could improve on existing information resources. The recommendations resulting from the survey and workshop discussions focused on the following: (1) developing a Central Subject Directory (CSD) for existing data, (2) standardizing data management forms and protocols used by different agencies, and (3) providing data management services for the TBNEP throughout its tenure. THE GLOBAL POTENTIAL ENERGY SURFACES OF THE LOWEST TWO 1A' STATES OF THE OZONE MOLECULE: THEORETICAL DETERMINATION AND ANALYSIS Ph.D. Thesis
Gregory John Atchity 1992 271 p
Avail. Univ. Microfilms Order No. DA9311473

The two lowest 1A' potential energy surfaces (PES) of the ozone molecule are determined and analyzed using accurate ab-initio MCSCF calculations. As appropriate internal coordinates, the shape-scale perimetric coordinates for triatomic molecules are discussed and further developed. Because the previously determined intersection between these two surfaces of like symmetry is unusual, much of the present work involves this intersection. The relevant theory of intersections is reviewed, and a method for characterizing intersections according to the topology of the surfaces in their vicinity is developed. Furthermore, the reasons for this particular crossing in ozone are investigated. The analysis is based on a method for transforming the adiabatic states produced by quantum chemical calculations into diabatic states. The method is founded on the idea that a diabatic state should be dominated throughout coordinate space by a single set of configurations. Accordingly, the transformation to diabatic states is derived by maximizing the contribution of these configurations to their respective states. It is shown that the crossing in ozone is due to an additional exchange in dominance of configurations within each diabatic state. The intersection point in C(sub 2v) symmetry is part of a larger, 1-dimensional intersection seam in C(sub s) symmetry. This seam is shown to consist of four branches, one of which is a closed loop. The three other branches lie entirely in C(sub 2v) restricted subspaces and connect to the first branch at nodes. Additional intersections must exist. A new method for determining an intersection point in a two-dimensional coordinate space, based on the wave function phase-change theorem of Herzberg-Longuet-Higgins, is also developed. Finally, global mappings of the two potential energy surfaces in the scale-shape perimetric coordinates are determined. The minima of the two surfaces, their dissociation and rearrangement paths, and the map of the energy difference between them are all discussed. It is shown that direct formation of the ring structure of ozone from O2 and O is improbable and that there is no rearrangement pathway on the ground state representing the interchange of two atoms. Dissert. Abstr.

TERMINAL DECOMPOSITION AND GASEOUS SULFUR RELEASE FROM TIDAL WETLANDS Final Technical Report, 1 Oct. 1983 - 31 May 1992
Mark E. Hines 1992 137 p
(Grant NAGw-0512)
(NASA-CR-193466; NAS 1.26:193466) Avail: CASI HC A07/MF A02

A summary of the results of a multi-year project which studied the release of biogenic sulfur gases from wetland habitats is reported. This project also included an initial study of factors that control terminal decomposition in temperate salt marsh sediments. This preliminary research was used as a biogeochemical foundation for the interpretation of data collected during other aspects of the work. As time progressed the research moved greatly into freshwaters since it became clear that these habitats had a greater influence on regional and global processes and these habitats were grossly understudied with respect to their role as producers and consumers of atmospheric S compounds. More detailed information is provided as appendices. For individual titles, see N94-12452 through N94-12470.

A PRELIMINARY STUDY OF THE VARIABILITY AND MAGNITUDE OF THE FLUX OF BIOGENIC SULFUR GASES FROM A NEW HAMPSHIRE SALT MARSH M.S. Thesis
Michael Cope Morrison *In its* Terminal Decomposition and Gaseous Sulfur Release from Tidal Wetlands 1992 2 p (For primary document see N94-12451 01-45)
Avail: CASI HC A01/MF A02

Salt marshes have highly variable spatial and temporal fluxes of hydrogen sulfide, carbonyl sulfide, methane thiol, dimethyl sulfide, and carbon disulfide (H2S, COS, MeSH, DMS, and CS2, respectively). This variability was tested at nine emission sites in a New Hampshire, USA salt marsh: three replicates in each of three vegetation zones, Spartina alterniflora, S. patens, and a transition zone. Three sites were sampled simultaneously, either within or across vegetation zones, using a dynamic flux chamber technique. Difficulties with calibration and field equipment resulted in fluxes with maximum absolute uncertainties of greater than plus or minus 200 percent. However, the relative uncertainty between subsequent samples was closer to plus or minus 20 percent. Chambers are expected to affect the natural flux of gases by altering the humidity, temperature, and composition of the gas inside the chamber. Summertime fluxes are highest for all gases except COS which demonstrated evidence of a springtime peak. A summertime background flux of 5 to 100 x 10(exp -9) g S/m(sup -2) min was observed for all gases, while S alternifora fluxes of MeSH and DMS were approximately 8 fold and approximately 100 fold higher than S. patens, respectively. DMS and MeSH fluxes were higher during the day than at night. Evidence of COS uptake by plants was observed. CS2 appeared to be the quantitatively least important sulfur gas emitted. Improved laboratory and sample collection techniques and further data collection in the field will yield information on the details of salt marsh variability, will improve estimates of the error associated with single flux measurements, and will allow a more accurate estimation of sulfur fluxes from salt marshes based on vegetation and area coverage data. Inability to control the temperature and humidity inside of the chamber remain significant problems with the chamber design. Author (revised)

SULFATE REDUCTION AND OTHER SEDIMENTARY BIOGEOCHEMISTRY IN A NORTHERN NEW ENGLAND SALT MARSH

Mark E. Hines, Stephen L. Knollmeyer, and Joyce B. Tugel *In its* Terminal Decomposition and Gaseous Sulfur Release from Tidal Wetlands 1992 23 p (For primary document see N94-12451 01-45)
(Grant NAGw-512)
Avail: CASI HC A03/MF A02

Sulfate reduction rates, dissolved iron and sulfide concentrations, and titration alkalinity were measured in salt marsh soils along a transect that included areas inhabited by both the tall and short forms of Spartina alterniflora and by Spartina patens. Pore waters were collected with in situ 'sippers' to acquire temporal data from the same location without disturbing plant roots. During 1984, data collected at weekly intervals showed rapid temporal changes in belowground biogeochemical processes that coincided with changes in S. alterniflora physiology. Rates of SO4(-2) reduction increased fivefold (to greater than 2.5 micromol ml(sup -1)d(sup -1)) when plants began elongating aboveground yet decreased fourfold upon plant flowering. This rapid increase in rates of SO4(-2) reduction must have been fueled by dissolved organic matter released from roots only during active growth. Once plants flowered, the supply of oxidants to the soil decreased and sulfide and alkalinity concentrations increased despite decreases in SO4(-2) reduction and increases in SO4(-2):Cl(-) ratios. Sulfide concentrations were highest in soils inhabited by tallest plants. During 1985, S. alterniflora became infested with fly larvae (Chaetopsis apicalis John) and aboveground growth ceased in late June. This cessation was accompanied by decreased rates of SO4(-2) reduction similar to those noted during the previous year when flowering occurred. After the fly infestation, the pore-water chemical profiles of these soils resembled profiles of soils inhabited by the short form of S. alterniflora. The SO4(-2) reduction rates in S. patens soils are the first reported. Rates were similar to those in S. alterniflora except that they did not increase greatly when S. patens was elongating. Tidal and rainfall events produced desiccation-saturation cycles that altered redox conditions in the S. patens soils, resulting in rapid changes in the dissolution and precipitation of iron and in the magnitude and spatial distribution of SO4(-2) reduction. THE ROLE OF CERTAIN INFAUNA AND VASCULAR PLANTS IN THE MEDIATION OF REDOX REACTIONS IN MARINE SEDIMENTS

Mark E. Hines *In its* Terminal Decomposition and Gaseous Sulfur Release from Tidal Wetlands 1992 12 p (For primary document see N94-12451 01-45)
(Grants NAGw-512; NSF OCE-80-18460; NSF OCE-82-14863; NSF OCE-85-15639)
Avail: CASI HC A03/MF A02

The mechanisms by which certain animals and plants affect redox processes in sediments was examined by studying three environments: (1) subtidal sediments dominated by the deposit-feeding polychaete Heteromastus filiformis; (2) a saltmarsh inhabited by the tall form of Spartina alterniflora; and (3) tropical carbonate sediments inhabited by three species of seagrasses. S-35-sulfide production rates were compared to pool sizes of dissolved sulfide and dissolved iron. In all of the sediments studied, rates of sulfide reduction were enhanced by macroorganisms while the rate of turnover of dissolved sulfide increased. The polychaete enhanced microbial activity and redox cycling primarily by subducting particles of organic matter and oxidized iron during sediment reworking. The Spartina species enhanced anaerobic activity by transporting primarily dissolved organic matter and oxidants. Although the final result of both animal and plant activities was the enhancement of sub-surface cycling of sulfur and iron, decreased dissolved sulfide and increased dissolved iron concentrations, the mechanisms which produced these results differed dramatically. Author (revised)

EMISSIONS OF BIOGENIC SULFUR GASES FROM ALASKAN TUNDRA

Mark E. Hines and Michael C. Morrison *In its* Terminal Decomposition and Gaseous Sulfur Release from Tidal Wetlands 1992 5 p (For primary document see N94-12451 01-45)
(Grant NAGw-512)
Avail: CASI HC A01/MF A02

Fluxes of the biogenic sulfur gases carbonyl sulfide (COS), dimethyl sulfide (DMS), methyl mercaptan (MeSH), and carbon disulfide (CS2) were determined for several freshwater and coastal marine tundra habitats using a dynamic enclosure method and gas chromatography. In the freshwater tundra sites, highest emissions, with a mean of 6.0 nmol/m(sup -2)H(sup -1) (1.5-10) occurred in the water-saturated wet meadow areas inhabited by grasses, sedges, and Sphagnum mosses. In the drier upland tundra sites, highest fluxes occurred in areas inhabited by mixed vegetation and labrador tea at 3.0 nmol/m(sup -2)h(sup -1) (0-8.3) and lowest fluxes were from lichen-dominated areas at 0.9 nmol/m(sup -2)h(sup -1). Sulfur emissions from a lake surface were also low at 0.8 nmol/m(sup -2)h(sup -1). Of the compounds measured, DMS was the dominant gas emitted from all of these sites. Sulfure emissions from the marine sites were up to 20-fold greater than fluxes in the freshwater habitats and were also dominated by DMS. Emissions of DMS were highest from intertidal soils inhabited by Carex subspathacea (150-250 nmol/m(sup -2)h(sup -1)). This Carex sp. was grazed thoroughly by geese and DMS fluxes doubled when goose feces were left within the flux chamber. Emissions were much lower from other types of vegetation which were more spatially dominant. Sulfure emissions from tundra were among the lowest reported in the literature. When emission data were extrapolated to include all tundra globally, the global flux of biogenic sulfur from this biome is 2-3 x 10(exp 8) g/yr. This represents less than 0.001 percent of the estimated annual global flux (approximately 50 Tg) of biogenic sulfur and less than 0.01 percent of the estimated terrestrial flux. The low emissions are attributed to the low availability of sulfate, certain hydrological characteristics of tundra, and the tendency for tundra to accumulate organic matter. Author (revised)

FACTORS CONTROLLING FLUXES OF VOLATILE SULFUR COMPOUNDS IN SPHAGNUM PEATLANDS Ph.D. Thesis

William Zamboni deMello *In its* Terminal Decomposition and Gaseous Sulfur Release from Tidal Wetlands 1992 2 p (For primary document see N94-12451 01-45)
Avail: CASI HC A01/MF A02

Exchange of DMS and OCS between the surface of Sphagnum peatlands and the atmosphere were measured with dynamic (S-free sweep air) and static enclosures. DMS emission rates determined by both methods were comparable. The dynamic method provided positive OCS flux rates (emission) for measurements performed at sites containing Sphagnum. Conversely, data from the static method indicated that OCS was consumed from the atmosphere. Short and long-term impacts of increased S deposition on fluxes of volatile S compounds (VSC's) from Sphagnum peatlands were

investigated in a poor fen (Mire 239) at the Experimental Lakes Area, Ontario, Canada. Additional experiments were conducted in a poor fen (Sallie's Fen in Barrington, NH, USA). At Mire 239, emissions of VSC's were monitored, before and after acidification, at control and experimental sections within two major physiographic areas of the mire (oligotrophic and minerotrophic). DMS was the predominant VSC released from Mire 239 and varied largely with time and space. Sulfur addition did not affect DMS emissions in a period of hours to a few days. DMS emissions in the experimental oligotrophic area of the mire was approximately 3-fold greater than in the control oligotrophic area, and approximately 10-fold greater than in the minerotrophic zones. These differences could be due to a combination of differences in types of vegetation, nutritional status, and S input. At Sallie's Fen, DMS fluxes were not significantly affected by sulfate amendments, while DMS and MSH concentrations increased greatly with time in the top 10 cm of the peat column. The major environmental factors controlling fluxes of DMS in a Sphagnum-dominated peatland were investigated in Sallie's Fen, NH. DMS emissions from the surface of the peatland varied greatly over 24 hours and seasonally. Temperature seemed to be the major environmental factor controlling these variabilities. Concentrations of dissolved VSC's varied with time and space throughout the fen. Dissolved DMS, MSH, and OCS in the surface of the water table were supersaturated with respect to their concentrations in the atmosphere. Sphagnum mosses did not appear to be a direct source of VSC's, however they increase transport of DMS from the peat surface to the atmosphere.

EMISSIONS OF SULFUR GASES FROM MARINE AND FRESHWATER WETLANDS OF THE FLORIDA EVERGLADES: RATES AND EXTRAPOLATION USING REMOTE SENSING

Mark E. Hines (New Hampshire Univ., Durham.), Ramona E. Pelletier, and Patrick M. Crill (New Hampshire Univ., Durham.) *In* New Hampshire Univ., Terminal Decomposition and Gaseous Sulfur Release from Tidal Wetlands 1992 8 p Sponsored by NASA. Washington (For primary document see N94-12451 01-45)
(Grants NAGw-512; NAGw-2771)
Avail: CASI HC A02/MF A02

Rates of emissions of the biogenic sulfur (S) gases carbonyl sulfide (COS), methyl mercaptan (MSH), dimethyl sulfide (DMS), and carbon disulfide (CS2) were measured in a variety of marine and freshwater wetland habitats in the Florida Everglades during a short duration period in October using dynamic chambers, cryotrapping techniques, and gas chromatography. The most rapid emissions of greater than 500 nmol/m(sup -2)h(sup -1) occurred in red mangrove-dominated sites that were adjacent to open seawater and contained numerous crab burrows. Poorly drained red mangrove sites exhibited lower fluxes of approximately 60 nmol/m(sup -2)h(sup -1) which were similar to fluxes from the black mangrove areas which dominated the marine-influenced wetland sites in the Everglades. DMS was the dominant organo-S gas emitted especially in the freshwater areas. Spectral data from a scene from the Landsat thematic mapper were used to map habitats in the Everglades. Six vegetation categories were delineated using geographical information system software and S gas emission were extrapolated for the entire Everglades National Park. The black mangrove-dominated areas accounted for the largest portion of S gas emissions to the area. The large area extent of the saw grass communities (42 percent) accounted for approximately 24 percent of the total S emissions.

EMISSIONS OF SULFUR GASES FROM WETLANDS

Mark E. Hines *In its* Terminal Decomposition and Gaseous Sulfur Release from Tidal Wetlands 1992 21 p (For primary document see N94-12451 01-45)
Avail: CASI HC A03/MF A02

Data on the emissions of sulfur gases from marine and freshwater wetlands are summarized with respect to wetland vegetation type and possible formation mechanisms. The current data base is largest for salt marshes inhabited by Spartina alterniflora. Both dimethyl sulfide (DMS) and hydrogen sulfide (H2S) dominate emissions from salt marshes, with lesser quantities of methyl mercaptan (MeSH), carbonyl sulfide (COS), carbon disulfide (CS2) and dimethyl disulfide (DMDS) being emitted. High emission rates of DMS are associated with vegetation that produces the DMS precursor dimethylsulfonionpropionate (DMSP). Although large quantities of H2S are produced in marshes, only a small percentage escapes to the atmosphere. High latitude marshes emit less sulfur gases than temperate ones, but DMS still dominates. Mangrove-inhabited wetlands also emit less sulfur than temperate S. alterniflora marshes. Few data are available on sulfur gas emissions from freshwater wetlands. In most instances, sulfur emissions from temperate freshwater sites are low. However, some temperate and subtropical freshwater sites are similar in magnitude to those from marine wetlands which do not contain vegetation that produces DMSP. Emissions are low in Alaskan tundra but may be considerably higher in some bogs and fens.

ACETATE CONCENTRATIONS AND OXIDATION IN SALT MARSH SEDIMENTS

In its Terminal Decomposition and Gaseous Sulfur Release from Tidal Wetlands 1992 32 p (For primary document see N94-12451 01-45)
(Grants NAGw-512; NSF OCE-85-18491; NSF OCE-84-15687; NSF OCE-86-15055)
Avail: CASI HC A03/MF A02

Acetate concentrations and rates of acetate oxidation and sulfate reduction were measured in S. alterniflora sediments in New Hampshire and Massachusetts. Pore water extracted from cores by squeezing or centrifugation contained in greater than 0.1 mM acetate and, in some instances, greater than 1.0 mM. Pore water sampled nondestructively contained much less acetate, often less than 0.01 mM. Acetate was associated with roots, and concentrations varied with changes in plant physiology. Acetate turnover was very low whether whole core or slurry incubations were used. Radiotracers injected directly into soils yielded rates of sulfate reduction and acetate oxidation not significantly different from core incubation techniques. Regardless of incubation method, acetate oxidation did not account for a substantial percentage of sulfate reduction. These results differ markedly from data for unvegetated coastal sediments where acetate levels are low, oxidation rate constants are high, and acetate oxication rates greatly exceed rates of sulfate reduction. The discrepancy between rates of acetate oxidation and sulfate reduction in these marsh soils may be due either to the utilization of substrates other than acetate by sulfate reducers or artifacts associated with measurements of organic utilization by rhizosphere bacteria. Care must be taken when interpreting data from salt marsh sediments since the release of material from roots during coring may affect the concentrations of certain compounds as well as influencing results obtained when sediment incubations are employed.

APPLICATION OF STATIC AND DYNAMIC ENCLOSURES IN DETERMINING DMS AND OCS FLUXES IN SPHAGNUM PEATLANDS
Abstract Only

William Zamboni deMello and Mark E. Hines *In its* Terminal Decomposition and Gaseous Sulfur Release from Tidal Wetlands 1992 1 p Submitted for publication (For primary document see N94-12451 01-45)
Avail: CASI HC A01/MF A02

A static enclosure method was applied to determine the exchange of dimethyl sulfide (DMS) and OCS between the surface of Sphagnum peatlands and the atmosphere. Measurements were performed concurrently with dynamic enclosure measurements with S-free air used as sweep gas. DMS emission rates determined by both methods were comparable between 5 and 500 nmol/m(sup -2)h(sup -1). The dynamic method provided positive OCS flux rates (emission) for measurements performed at sites containing Sphagnum. Conversely, data from the static method indicated that OCS was consumed from the atmosphere. Measurements using both techniques at a site devoid of vegetation showed that peat is a source of both DMS and OCS. Results suggested that OCS is produced in surface peat but it is taken up from the atmosphere by Sphagnum mosses. However, the net effect of both processes is that OCS uptake exceeds emission. The dynamic enclosure technique is adequate to measure rates of emissions of S gases which are produced in peatlands but not consumed, as long as attention is paid to the rate of sweep flow.

EFFECTS OF INORGANIC SULFUR ADDITION ON FLUXES OF VOLATILE SULFUR COMPOUNDS IN SPHAGNUM PEATLANDS Abstract Only

William Zamboni deMello, Mark E. Hines, and Suzanne E. Bayley (Alberta Univ., Edmonton.) *In its* Terminal Decomposition and Gaseous Sulfur Release from Tidal Wetlands 1992 1 p Submitted for publication (For primary document see N94-12451 01-45)

Avail: CASI HC A01/MF A02

Short and long-term impacts of increased S deposition on fluxes of volatile S compounds (VSC's) from Sphagnum peatlands were investigated in an artificially acidified (sulfuric and nitric acids) poor fen (Mire 239) at the Experimental Lakes Area (ELA), Ontario, Canada. Additional experiments were conducted in a poor fen (Sallie's Fen) in Barrington, NH, USA. At Mire 239, emissions of VSC's were monitored, before and after acidification, at control (unacidified) and experimental sections within two major physiographic zones of the mire (oligotrophic and minerotrophic). The experimental segments of the mire received S amendments since 1983, in amounts equivalent to the annual S deposition in the highest polluted areas of Canada and U.S. Dimethyl sulfide (DMS) was the predominant VSC released from the mire and varied largely with time and space (i.e., from 2.5 to 127 nmol/m(sup -2)h(sup -1)). Sulfur addition did not affect DMS emissions in a period of hours to a few days, although it stimulated production of DMS and MSH in the anoxic surficial regions of the peat. DMS emissions in the experimental oligotrophic segment of the mire was approximately 3-fold greater than in the control oligotrophic segment, and approximately 10-fold greater than in the minerotrophic zones. These differences could be due to a combination of differences in types of vegetation, nutritional status, and S input. At Sallie's Fen, DMS fluxes were approximately 8 times higher from a Sphagnum site than from a bare peat site. Fluxes of VSC's were not significantly affected by sulfate amendments at both sites, while DMS and MSH concentrations increases greatly with time in the top 10 cm of the peat column. Our data indicated that although Sphagnum is not the direct source of DMS released from Sphagnum peatlands, it might play a role in regulating DMS emissions to the atmosphere. Author (revised)

ENVIRONMENTAL FACTORS CONTROLLING FLUXES OF DIMETHYL SULFIDE IN A NEW HAMPSHIRE FEN Abstract Only

William Zamboni deMello and Mark E. Hines *In its* Terminal Decomposition and Gaseous Sulfur Release from Tidal Wetlands 1992 2 p Submitted for publication (For primary document see N94-12451 01-45)
(Grant NAGw-0512)

Avail: CASI HC A01/MF A02

The major environmental factors controlling fluxes of dimethyl sulfide (DMS) in a Sphagnum-dominated peatland were investigated in a poor fen in New Hampshire. DMS emissions from the surface of the peatland varied greatly over 24 hours and seasonally. Maximum DMS emissions occurred in summer with minima in the late fall. Temperature was the major environmental factor controlling these variabilities. There was also some evidence that the changes in water table height might have contributed to the seasonable variability in DMS emission. The influence of the water table was greater during periods of elevated temperature. DMS and MSH were the most abundant dissolved volatile sulfur compound (VSC) in the surface of the water table. Concentrations of dissolved VSC's varied with time and space throughout the fen. Dissolved MDS, MSH, and OCS in the surface of the water table were supersaturated with respect to their concentrations in the atmosphere suggesting that the peat surface was a source of VSC's in the peatland. VCS in peatlands seemed to be produced primarily by microbial processes in the anoxic surface layers of the peat rich in organic matter and inorganic sulfide. Sphagnum mosses were not a direct source of VSC's. However, they increased transport of DMS from the peat surface to the atmosphere. Author (revised)

SULFUR TRANSFORMATIONS IN THE SEDIMENTS OF A NEW HAMPSHIRE SALT MARSH Abstract Only

Mark E. Hines, S. L. Knollmeyer, A. Eldridge, D. Luken, Joyce B. Tugel, and W. Berry Lyons *In its* Terminal Decomposition and Gaseous Sulfur Release from Tidal Wetlands 1992 1 p (For primary document see N94-12451 01-45)

Avail: CASI HC A01/MF A02

Summer sulfate reduction and sulfide and iron chemistry were monitored in marsh soils along a gradient from a creekside Spartina alterniflora region to an inland area dominated by S. patens. Sulfate reduction rates measured using S-35 increased from 0.4 in June to as much as 4.5 micro-mole/ml(sup -1)d(sup -1) in July in S. alterniflora soils with most rapid rates occurring in the upper few cm. Rates in S. patens soils were approximately equal to 5-8 fold slower with the most rapid rates occurring generally in soils deeper than 10 cm. The recovery percentage of reduced S-35 sulfur varied with depths at both locations; dissolved and acid-volatile sulfides dominating S. alterniflora regions while chromium-reducible solid phases were abundant in S. patens soils. Dissolved sulfide in S. alterniflora soils increased throughout the summer to approximately equal to 2.8 mM while sulfide in S. patens soils was abundant only in soils deeper than 15 cm. Dissolved sulfide covaried inversely with iron. Diel studies demonstrated that sulfide and iron varied approximately equal to two-fold in response to a semi-diurnal tide. Dissolved sulfide turnover was most rapid during periods of active plant growth. Author (revised)

BIOGEOCHEMICAL FACTORS WHICH REGULATE THE FORMATION AND FATE OF SULFIDE IN WETLANDS

Mark E. Hines, W. Berry Lyons, and H. E. Gaudette *In its* Terminal Decomposition and Gaseous Sulfur Release from Tidal Wetlands 1992 12 p Submitted for publication (For primary document see N94-12451 01-45)

Avail: CASI HC A03/MF A02

Coastal wetland areas occupy a small percentage of the terrestrial environment yet are extremely productive regions which support rapid rates of belowground bacterial activity. Wetlands appear to be significant as biogenic sources of gaseous sulfur, carbon, and nitrogen. These gases are important as tracers of man's activities, and they influence atmospheric chemistry. The interactions among wetland biogeochemical processes regulate the anaerobic production of reduced gases and influence the fate of these volatiles. Therefore, spatial and temporal variations in hydrology, salinity, temperature and specification, and growth of vegetation affect the type and magnitude of gas emissions thus hindering predictive estimates of gas flux. Our research is divided into two major components, the first is the biogeochemical characterization of a selected tidal wetland area in terms of factors likely to regulate sulfide flux; the second is a direct measurement of gaseous sulfur flux as related to changes in these biogeochemical conditions. Presently, we are near completion of phase one. Author (revised)

THE EFFECTS OF ACID DEPOSITION ON SULFATE REDUCTION AND METHANE PRODUCTION IN PEATLANDS Abstract Only

Georgia L. Murray, Mark E. Hines, and Suzanne E. Bayley (Alberta Univ., Edmonton.) *In its* Terminal Decomposition and Gaseous Sulfur Release from Tidal Wetlands 1992 1 p Presented at the Gordon Research Conference on Hydrological/Geological/Biological Interactions in Forested Catchments, Plymouth, NH, 1991 (For primary document see N94-12451 01-45)

Avail: CASI HC A01/MF A02

Peatlands, as fens and bods, make up a large percentage of northern latitude terrestrial environments. They are organic rich and support an active community of anaerobic bacteria, such as methanogenic and sulfate-reducing bacteria. The end products of these microbial activities, methane and hydrogen sulfide, are important components in the global biogeochemical cycles of carbon and sulfur. Since these two bacterial groups compete for nutritional substrates, increases in sulfate deposition due to acid rain potentially can disrupt the balance between these processes leading to a decrease in methane production and emission. This is significant because methane is a potent greenhouse gas that effects the global heat balance. A section of Mire 239 in the Experimental Lakes Area, in Northwestern Ontario, was artificially acidified and rates of sulfate reduction and methane production were measured with depth. Preliminary results suggested that methane production was not affected immediately after acidification. However, concentrations of dissolved methane decreased and dissolved sulfide increased greatly after acidification and both took several days to recover. The exact mechanism for the decrease in methane was not determined. Analyses are under way which will be used to determine rates of sulfate reduction. These results will be available by Spring and will be discussed. Author

DMS EMISSIONS FROM SPHAGNUM-DOMINATED WETLANDS Abstract Only

Mark E. Hines, William Zamboni deMello, and Suzanne E. Bayley *In its* Terminal Decomposition and Gaseous Sulfur Release from Tidal Wetlands 1992 1 p (For primary document see N94-12451 01-45)

Avail: CASI HC A01/MF A02

The role of terrestrial sources of biogenic S and their effect on atmospheric chemistry remain as major unanswered questions in our understanding of the natural S cycle. The role of northern wetlands as sources and sinks of gaseous S was investigated by measuring rates of S gas exchange as a function of season, hydrologic conditions, and gradients in trophic status. Experiments were conducted in wetlands in New Hampshire (NH), and in Mire 239, a poor fen at the Experimental Lakes Area (ELA) in Ontario. Emissions were determined using Teflon enclosures, gas cryotrapping methods, and GC with flame photometric detection. Emissions of DMS dominated fluxes. In NH, DMS fluxes were greater than 1.6 micromol/m(sup -2)d(sup -1) in early summer, 1989 when temperatures were warm and the water table was approximately 5 cm below the surface. These rates are several-fold faster than average oceanic rates of DMS emission. A rapid drop in the water table resulted in a 6-fold decrease in DMS emissions in late July. In 1990, a new beaver dam kept water levels above the surface and S emissions were much lower than during 1989. The elimination of the beaver and a drop in the water table in August produced a rapid increase in S gas emissions. Emissions of DMS were highest in the most oligotrophic areas. Mire 239 (ELA) was irrigated with sulfuric and nitric acids to simulate acid rain. S emissions were determined before and after an acidification event in control and experimental areas in both minerotrophic and oligotrophic regions. Emissions of DMS were higher in the acidified areas compared to unacidified controls. Emissions were also much higher in the oligotrophic regions compared to the minerotrophic ones. Despite the wide differences in S gas fluxes (20-fold), it was difficult to determine whether acidification or variations in trophic status was not responsible for differences in S gas emissions. DMS emitted into the atmosphere was not derived from the water table but originated in peat in the unsaturated zone. Author (revised)

Acetate is important in anaerobic metabolism of non-vegetated sediments but its role in salt marsh soils was not investigated thoroughly. Acetate concentrations, oxidation (C-14) and SO4(2-) reduction (S-35) were measured in S. alterniflora soils in NH and MA. Pore water from cores contained greater than 0.1 mM acetate and in some instances greater than 1.0 mM. Non-destructive samples contained less than 0.01 mM. Acetate was associated with roots and concentrations were highest during vegetative growth and varied with changes in plant physiology. Acetate turnover was very low whether whole core or slurry incubations were used. Radiotracers injected directly into soils yielded rates of SO4(2-) reduction and acetate oxidation not significantly different from core incubation techniques. Regardless of incubation method, acetate oxidation did not account for a significant percentage of SO4(2-) reduction. These results differ markedly from data for non-vegetated coastal sediments where acetate levels are low, oxidation rate constants are high and acetate oxidation rates greatly exceed rates of SO4(2-) reduction. The discrepancy between rates of acetate oxidation and SO4(2-) reduction in marsh soils may be due either to the utilization of substrates other than acetate by SO4(2-) reducers or artifacts associated with measurements of organic utilization by rhizosphere bacteria. FACTORS CONTROLLING SULFUR GAS EXCHANGE IN SPHAGNUM-DOMINATED WETLANDS

William Zamboni deMello, Mark E. Hines, and Suzanne E. Bayley (Alberta Univ., Edmonton.) *In its* Terminal Decomposition and Gaseous Sulfur Release from Tidal Wetlands 1992 1 p (For primary document see N94-12451 01-45)

Avail: CASI HC A01/MF A02

Atmosphere-peatland exchange of reduced sulfur gases was determined seasonally in fen in NH, and in an artificially-acidified fen at the Experimental Lakes Area (ELA) in Canada. Dimethyl sulfide (DMS) dominated gas fluxes at rates as high as 400 nmol/m(sup -2)hr(sup -1). DMS fluxes measured using enclosures were much higher than those calculated using a stagnant-film model, suggesting that Sphagnum regulated efflux. Temperature controlled diel and seasonal variability in DMS emissions. Use of differing enclosure techniques indicated that vegetated peatlands consume atmospheric carbonyl sulfide. Sulfate amendments caused DMS and methane thiol concentrations in near-surface pore waters to increase rapidly, but fluxes of these gases to the atmosphere were not affected. However, emission data from sites experiencing large differences in rates of sulfate deposition from the atmosphere suggested that chronic elevated sulfate inputs enhance DMS emissions from northern wetlands. COMMENTS ON POSSIBLE CAUSES OF RECENT GLOBAL WARMING

P. B. Duffy 24 Sep. 1992 9 p Presented at the 73rd AMS Meeting, Anaheim, CA, 17-22 Jan. 1992

(Contract W-7405-eng-48)

(DE93-010501; UCRL-JC-110846; CONF-9201148-1) Avail: CASI HC A02/MF A01

The researcher shows that recent global temperature changes cannot be due to solar luminosity variations coincident with changes in solar cycle amplitudes, since this would violate causality. In addition, a related suggestion using solar cycle lengths instead of amplitudes appears highly unlikely, since time lags between changes in the cycle lengths and observed temperatures are very different from those calculated with a climate model. Finally, lag correlations between historical land and sea temperates indicate that ocean temperatures follow land temperatures by 15 or 20 yr. This means that the oceans' response time must be at least this long, if these temperature changes are due to some change in external forcing. It also suggests that this is in fact the case, since 'natural' climate variations might well entail SST's changing beforeLAT's, which is not observed.

NOVEL MASS SPECTROMETRIC INSTRUMENT FOR GASEOUS AND PARTICULATE CHARACTERIZATION AND MONITORING

M. J. Coggiola Feb. 1993 15 p

(Contract DE-AC21-92MC-29116)

(DE93-014093; DOE/MC-29116/3355) Avail: CASI HC A03/MF A01

SRI International will develop a unique new instrument that will be capable of providing real-time, quantitative, chemical characterization of gaseous and particulate pollutants generated from DOE waste cleanup activities. The instrument will be capable of detecting and identifying volatile organic compounds, polynuclear aromatic hydrocarbons, heavy metals, and transuranic species released during waste cleanup activities. The instrument will be unique in its ability to detect and quantify in real-time these diverse pollutants in both vapor and particulate form. The function of the sampler is to obtain a sufficient and representative quantity of air pollutants from a wide range of waste cleanup activities, both vapor and particulate. In addition, the sampler must deliver the vapors and particles to the detection instrument with minimal material loss. DOE

AMIP: THE ATMOSPHERIC MODEL INTERCOMPARISON PROJECT
W. L. Gates Dec. 1992 20 p
(Contract W-7405-eng-48)
(DE93-007400; UCRL-ID-111532-Rev-1; PCMDI-7) Avail: CASI HC A03/MF A01

The Atmospheric Model Intercomparison Project (AMIP) is an international effort to determine the systematic climate errors of atmospheric models under realistic conditions. The AMIP requires the simulation of the climate of the decade 1979-1988 using the observed monthly-averaged distributions of sea-surface temperature and sea ice as boundary conditions. Organized by the Working Group on Numerical Experimentation (WGNF) as a contribution to the World Climate Research Programme, AMIEP involves the international atmospheric modeling community in a major test and intercomparison of model performance; in addition to an agreed-to set of monthly-averaged output variables, each of the participating models will generate a daily history of state. These data will be stored and made available in standard format by the Program for Climate Model Diagnosis and Intercomparison (PCMDI) at the Lawrence Livermore National Laboratory. Following completion of the computational phase of AMIP in 1993, emphasis will shift to a series of diagnostic subprojects, now being planned, for the detailed examination of model performance and the simulation of specific physical processes and phenomena. AMIP offers an unprecedented opportunity for the comprehensive evaluation and validation of current atmospheric models and is expected to provide valuable information for model improvement. DOE

THE LATHROP WELLS VOLCANIC CENTER: STATUS OF FIELD AND GEOCHRONOLOGY STUDIES
B. Crowe, R. Morley, S. Wells (California Univ., Riverside.), J. Geissman, E. McDonald, L. McFadden, and F. Perry (New Mexico Univ., Albuquerque.) 1993 16 p
(Contract W-7405-eng-36)
(DE93-008917; LA-Sub-93-51) Avail: CASI HC A03/MF A01

The Lathrop Wells volcanic center is located 20 km south of the potential Yucca Mountain site, at the south end of the Yucca Mountain range. It has long been recognized as the youngest basalt center in the region. However, determination of the age and eruptive history of the center has proven problematic. The purpose of this paper is to describe the status of field and geochronology studies of the Lathrop Wells center. Our perspective is that it is critical to assess all possible methods for obtaining cross-checking data to resolve chronology and field problems. It is equally important to consider application of the range of chronology methods available in Quaternary geologic research. Such an approach seeks to increase the confidence in data interpretations through obtaining convergence among separate isotopic, radiogenic, and age-correlated methods. Finally, the assumptions, strengths, and weaknesses of each dating method need to be carefully described to facilitate an impartial evaluation of results. DOE

A STUDY OF THE MAGNETIC FIELD ANNIHILATION PROCESS IN THE MAGNETOSPHERE AND SOME GEOTECHNICAL APPLICATIONS
1993 7 p
(Contract DE-FG06-86ER-13530)
(DE93-013248; DOE/ER-13530/6; GI-91-75a) Avail: CASI HC A02/MF A01

Our proposed project is to study the magneto reconnection processes in the Earth's magnetosphere by using both analytical methods and computer simulations. The three-dimensional (3-D) topology of the reconnected field lines and the kinetic aspects of magnetic reconnection in the collisionless magnetosphere are emphasized in the present study. At the dayside magnetopause magnetic flux ropes can form as a result of multiple X-line reconnection. Our 3-D MHD simulation shows that for an appropriate extent and location of two neighboring X-lines, a simple magnetic topology can be expected, in which the major amount of magnetic flux of the rope is connected at each end to only one side of the current sheet. This simple rope is different from the 'frayed' rope which has a complicated field topology. For a sufficient relative shift of the X-lines magnetic flux may enter a flux rope from the magnetosphere and exit into the magnetosphere, leading to the formation of magnetic flux ropes which contain a considerable amount of magnetosheath plasma on closed magnetospheric field lines. This process may provide a possible explanation for the formation of fossil

flux transfer events in the magnetosphere and the formation of the low latitude boundary layer.

DEVELOPMENT OF A BALLOON-BORNE STABILIZED PLATFORM FOR MEASURING RADIATIVE FLUX PROFILES IN THE ATMOSPHERIC BOUNDARY LAYER
C. D. Whiteman, J. M. Alzheimer, G. A. Anderson, and W. J. Shaw Mar. 1993 7 p Presented at the 3rd ARM Science Team Meeting, Norman, OK, 1-5 Mar. 1993, 1-5 Mar. 1993
(Contract DE-AC06-76RL-01830)
(DE93-013186; PNL-SA-21966; CONF-9303122-2) Avail: CASI HC A02/MF A01

A stabilized platform has been developed to carry broadband short-wave and long-wave radiometric sensors on the tetherline of a small tethered balloon that ascends through atmospheric depths of up to 1.5 km to obtain vertical profiles of radiative flux and flux divergence for evaluating atmospheric radiative transfer models. The Sky Platform was designed to keep the radiometers level despite unpredictable movements of the balloon and tetherline occasioned by turbulence and wind shear. The automatic control loop drives motors, gears, and pulleys located on two of the vertices of the triangular frame to climb the harness lines to keep the platform level. Radiometric sensors, an electronic compass, and an on-board data acquisition system make up the remainder of the Sky Platform. Because knowledge of the dynamic response of the tether line-platform system is essential to properly close the automatic control loop on the Sky Platform, a Motion Sensing Platform (MSP) was developed to fly in place of the Sky Platform on the tetherline to characterize the Sky Platform's operating environment. This unstabilized platform uses an array of nine solid-state linear accelerometers to measure the lateral and angular accelerations, velocities, and displacements that the Sky Platform will experience. This paper presents field performance tests of the Sky and Motion Sensing Platforms, as conducted at Richland, Washington, on February 17, 1993. The tests were performed primarily to characterize the stabilization system on the Sky Platform. Test flights were performed on this cold winter day from 1400 to 1800 Pacific Standard Time (PST). During this period, temperature profiles were near the dry adiabatic lapse rate. Flights were made through a jet wind speed profile having peak wind speeds of 7 m/s at a height of 100 m AGL. Wind directions were from the northwest. All flights were performed as continuous ascents, rather than ascending in discrete steps with halts at set altitudes.

RADIOGENIC AGE AND ISOTOPIC STUDIES
1992 259 p
(DE93-610548; GSCAN-P-91-2) Avail: CASI HC A12/MF A03 (US Sales Only)

This is one of an annual collection of reports presenting data from the Geochronology Section of the Continental Geoscience Division of the Geological Survey of Canada (GSC). The main purpose of this collection is to make geochronological and other radiogenic isotope data produced by the section available promptly to the geological community. Reports make full presentation of the data, relate these to field settings, and make comparatively short interpretations. Other geochronological and isotope data produced in the laboratory but published in outside journals or separate GSC publications are summarized at the end of this report. Report 5 contains 24 papers from most regions of Canada, but particularly from British Columbia. The Geochronology Laboratory has, over the years, provided substantial U-Pb dating for the Cordilleran Division of the Geological Survey of Canada in Vancouver, and the results of a number of these studies are presented this year. A compilation of K-Ar ages is given.

REVIEW OF SHARC 2.0 O3 KINETICS AND SPECTROSCOPY
Valerie I. Lang 1 Apr. 1993 28 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F04701-88-C-0089)
(AD-A265481; TOR-93(3078)-1) Avail: CASI HC A03

A critical review of rate constants assigned to vibrational excitation and de-excitation processes for O3 in the Strategic High Altitude Atmospheric Radiance Code (SHARC 2.0) is presented. A complete list of O3 pure rotational and rovibrational band parameters, based on the 1991/92 version of the HITRAN data base, is included. Modifications to specific energy transfer processes used in the SHARC 2.0 scheme have been recommended based on recent experimental literature data and on recent atmospheric observations.

COMPUTER MODELS USED TO SUPPORT CLEANUP DECISION-MAKING AT HAZARDOUS AND RADIOACTIVE WASTE SITES Final Report
Mar. 1993 113 p Prepared in cooperation with DOE, Washington, DC, and Nuclear Regulatory Commission, Washington, DC Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-183333; EPA/402/R-92/005) Avail: Issuing Activity (National Technical Information Service (NTIS))

To identify computer models actually being used to support decision-making at hazardous and radioactive waste sites, the EPA, DOE, and NRC jointly funded a study. The purpose was to identify models being used for hazardous and radioactive waste site assessment and describe and classify these models. Approximately 550 surveys were mailed to people engaged in cleanups at hazardous and radioactive waste sites. Responses were received from 87. The respondents identified 127 computer models used at EPA Superfund, DOE, and NRC sites. The models included multi-media models, ground water models, air models, engineering models, surface water models, geochemical models, and utility models. The responses revealed that few models were used across a large number of sites. In contrast, the results suggested that most cleanup efforts employed site-specific models.

IN SITU DETECTION OF TROPOSPHERIC OH, HO2, NO2, AND NO BY LASER-INDUCED FLUORESCENCE IN DETECTION CHAMBERS AT REDUCED PRESSURES Final Report, 1 Oct. 1989 - 31 Mar. 1993
William H. Brune 24 Jun. 1992 60 p
(Grant NAG1-1057)
(NASA-CR-193189; NAS 1.26:193189) Avail: CASI HC A04/MF A01

For detection of OH and HO2, we have met or exceeded most of the goals of the proposal for this grant. We have succeeded in building a prototype instrument for the detection of OH and HO2 that has a detection sensitivity of about 2 x 10 exp 4 (OH molecules/cc)/(ct/s), about five times greater than proposed. The current minimum detectable OH of 1.4 x 10 exp 5 OH molecules/cc (S/N=2; 30 second integration) is less than half that proposed, and will be much lower once scattered light levels are reduced. The instrument displays other important properties. First, interfering signals from other gases and OH losses on the inlet appear to be small under laboratory and field conditions. Second, three different calibration methods, two external to the inlet, give similar results, to within 30 percent. Third, the chemical conversion efficiency of HO2 to OH by addition of reagent NO is better than 90 percent. All of these factors give us great confidence that this technique works. The instrument has gone through several variations that have not affected its potential performance but have affected its use. We were able to undergo the first field trials away from State College in June 1992, when we were able to participate informally in the ROSE experiment in rural Alabama, a year ahead of the proposed schedule for field studies. Because this field experiment was our first and the data analysis was complicated by instrument instabilities, we have not yet released the observations. None-the-less, we have gained insight into instrument design. We have not yet completed all of the proposed work. The calibration systems need to be improved to reduce the 50 percent to 100 percent uncertainties to less than 30 percent. Interference signals from ambient gases and possible losses on the inlet under field conditions need to be quantified. Finally, the detection of NO2 and NO with laser induced fluorescence is only now being seriously pursued.

INVESTIGATION OF PASSIVE ATMOSPHERIC SOUNDING USING MILLIMETER AND SUBMILLIMETER WAVELENGTH CHANNELS Semiannual Status Report No. 5, 1 Jan. - 30 Jun. 1993

A. J. Gasiewski, L. K. Adelberg, D. B. Kunkee, and D. M. Jackson 1993 69 p
(Grant NAG5-1490)
(NASA-CR-193627; NAS 1.26:193627) Avail: CASI HC A04/MF A01

Progress by investigators at the Georgia Institute of Technology in the development of techniques for passive microwave retrieval of water vapor, cloud, and precipitation parameters using millimeter- and sub-millimeter wavelength channels is reviewed. Channels of particular interest are in the tropospheric transmission windows at 90, 166, 220, 340, and 410 GHz and centered around the water vapor lines at 183 and 325 GHz. Collectively, these channels have potential application in high-resolution mapping (e.g., from geosynchronous orbit), remote sensing of cloud and precipitation parameters, and retrieval of water vapor profiles. During the period from 1 Jan. 1993 through 30 Jun. 1993 the Millimeter-wave Imaging Radiometer (MIR) completed data flights during a two-month long deployment in conjunction with TOGA/COARE. Coincident data was collected from several other ground-based, airborne, and satellite sensors, including the NASA/MSFC AMPR, MIT MTS, DMSP SSM/T-2 satellite, collocated radiosondes, ground- and aircraft-based radiometers and cloud lidars, airborne infrared imagers, solar flux probes, and airborne cloud particle sampling probes. IMAGING OF MAGNETOSPHERIC DYNAMICS USING LOW ENERGY NEUTRAL ATOM DETECTION
H. O. Funsten, D. J. McComas, K. R. Moore, and E. E. Scime 1993 19 p Presented at the AGU Monograph/Solar System Plasma Physics Meeting on Resolution of Processes in Space and Time, Yosemite, CA, Feb. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-36)
(DE93-012656; LA-UR-93-1241; CONF-9302115-1) Avail: CASI HC A03

Recent advances in low energy neutral atom (LENA) detection technology show that magnetospheric imaging is achievable with 4(sub o)(times)4(sub o) resolution and can distinguish numerous features of the magnetosphere. A critical factor in detecting low energy neutrals is their removal from the ambient UV background. One technique to accomplish this is by ionizing the neutrals by their transmission through an ultrathin charge modification foil and subsequent electrostatic deflection. In this type of instrument, the driving factor for resolution and sensitivity is scattering in the foil and the ionization probability of transiting neutrals. We describe results of a prototype LENA imager using a collimated beam of 10 keV H. Additionally, we illustrate model results of anticipated LENA images of the magnetosphere based on the Rice Convection Model and show that plasma variations resulting from geomagnetic storm disturbances can be observed using a LENA imager. CLASSICAL GRAVITY COUPLED TO LIOUVILLE THEORY
F. D. Mazzitelli and N. Mohammedi (Bonn Univ., Germany.) Sep. 1992 22 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-613049; IC-92/292) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

The two dimensional Jackiw-Teitelboim model of gravity is considered. We first couple the model to the Liouville action and c scalar fields and show, treating the combined system as a nonlinear sigma model, that the resulting theory can be interpreted as a critical string moving in a target space of dimension $D = c + 2$. We then analyze perturbatively a generalized model containing a kinetic term and an arbitrary potential for the auxiliary field. We use the background field method and work covariant gauges. We show that the renormalizability of the theory depends on the form of the potential. For a general potential, the theory can be renormalized as a nonlinear sigma model. In the particular case of a Liouville-like potential, the theory is renormalized in the usual sense. DOE

SOME RESULTS WITH THE NEW DIGITAL IONOSONDE IN SAN DIEGO
A. K. Paul and R. A. Sprague Jan. 1993 3 p
(AD-A265178) Avail: CASI HC A01/MF A01

The new digital ionosonde (Dynasonde) became operational in early March 1992. The system takes ionograms in five minute intervals and the data are processed, extracting F-region profile and propagation parameters on a routine basis. The data verify earlier findings that a minimum sampling rate of twelve ionograms per hour is necessary to avoid aliasing. The most surprising result to date is the observation of large variations of the height of the F-region maximum (of the order of 100 km) during the nighttime hours of otherwise undisturbed days in late March and early April. The observed height variations are quasi-periodic, with periods of two to three hours and appear to have little effect on the F-region maximum electron density. DTIC

WAVE PROPAGATION CHARACTERISTICS OF SHORT-PERIOD CRUSTAL PHASES NEAR ARCESS AND NORESS Final Report, 1 May 1991 - 31 Oct. 1992
Kristin S. Vogfjord and Charles A. Langston Feb. 1993 54 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F19628-90-K-0044)
(AD-A265959; PL-TR-93-2034) Avail: CASI HC A04

Wave propagation of crustal phases near the ARCESS array is examined and compared to characteristics near the NORESS array, with emphasis on Lg and its composition. An f-k analysis is applied to the data to identify arrivals in the records. Then a composite of array beams is used to approximate each event. Record sections of composite-seismograms are constructed for different directions from ARCESS, to study propagational characteristics with distance and azimuth. Near surface velocity under NORESS and ARCESS is obtained through inversion of Rg wave dispersion curves. A composite ARCESS record section is compared to a NORESS record section of events located in the Caledonides. The differences that emerge are that Lg in the Caledonian region, north of NORESS, is dominated by discrete arrivals representing Moho reflections, with the order of reflection increasing with distance. In the Archean ARCESS region, however, Lg is dominated by turning waves, also with the order of reverberation increasing with distance, but with each confined to a small distance range. Rg wave propagation in the ARCESS region is much more efficient than in the Caledonian NORESS region, as Rg is observed to 400 km distance at ARCESS, but only to 200 km distance at NORESS. Synthetic record sections are constructed by wavenumber integration in order to model the observed character of Lg and Rg in the two regions. The dominating factor in the difference of Lg characteristics turns out to be the velocity gradient in the lower crust. A few earthquakes near ARCESS are also studied. Their depths can be constrained on the basis of phase velocities and depth phases. For reliable phase identification, however, the composition of Lg in the region needs to be accurately known. DTIC

A STUDY ON THE MAGNETOSPHERIC ACTIVITY USING THE AE, ap, AND Dst GEOMAGNETIC INDICES M.S. Thesis [ESTUDO DA ATIVIDADE MAGNETOSFERICA ATRAVES DOS INDICES GEOMAGNETICOS AE, AP E DST]

Marcelo MagalhaesFaresSaba Nov. 1992 123 p In PORTUGESE

(INPE-5470-TDI/501) Avail: CASI HC A06/MF A02

The usage of the geomagnetic indices AE, Dst and Kp (and its linear form ap) in studies of the earth's magnetic field variability is vast. However the relationship between them has been poorly studied. In this work different averages and correlations are done with these indices for the years 1974 (near solar minimum) and 1979 (solar maximum). A better understanding of magnetospheric activity monitoring, the relationships between these indices as well as of their uses and limitations is achieved. The correlations apx-Dst, AEx-Dst, apxAE and, for the first time, a multiple correlation apxAEx-Dst are done for different time intervals and levels of geomagnetic activity. In general, better correlations are found for the year 1974 and for the periods of geomagnetic storms. Furthermore, a study on the value of the minimum Dst and the correspondent maximum ap for storms and on two previous studies on the behavior of AE during the main phase of major magnetic storms are done. These studies make possible a better understanding of the storm/substorm relations and the estimation of indices when one of them is missing. Author (revised)

THE IMPACT OF HORIZONTAL RESOLUTION ON MOIST PROCESSES IN THE ECMWF MODEL

T. J. Phillips, L. C. Corsetti, and S. L. Grotch Jan. 1993 39 p

(Contract W-7405-eng-48)

(DE93-011718; UCRL-ID-112719; PCMDI-8) Avail: CASI HC A03/MF A01

Summer and winter climates simulated at spectral scales T21, T42, T63 and T106 with the ECMWF model are analyzed to determine the impact of changes in horizontal resolution on atmospheric water vapor, clouds, convection, and precipitation. Qualitative changes in Pi many moist processes occur in the transition from spectral T21 to T42, especially in the tropics where atmospheric convection plays a central role. However, the seasonal climate simulations do not show evidence of convergence to an asymptotic climate state at high resolution. Global convective precipitation increases monotonically with resolution, but frontal precipitation, precipitable water, and cloud cover display a qualitatively different pattern; after undergoing abrupt reductions in the transition from T21 to T42, their global averages show relative increases at finer resolutions. Precipitable water and cloud cover also display a seasonal asymmetry in their responses to increasing resolution. The comparative insensitivity of global cloud cover to resolution is mainly a consequence of compensating tendencies of clouds in different regions. With increasing resolution, decreases in low latitude clouds that result from drying of the tropical atmosphere are partially offset by increases in high-latitude clouds associated with enhanced relative humidity in response to an intensifying extratropical cold bias. The large-scale tropical moist processes are modeled more realistically at T21 than in the finer-resolution simulations, wherein anomalous seasonal climatic features such as a double ITCZ and underdeveloped summer monsoon circulation are evident. Although some of these anomalies might ameliorate if the physical parameterizations were suitably 'tuned,' these deficiencies may reflect more fundamental problems related to a mismatch between the resolution of the model and the implicit spatial and temporal scales of the parameterizations. Radiation fields from a perpetual July integration of a T106 version of the ECM-WF operational model are used to identify the most appropriate way to diagnose cloud radiative forcing in a general circulation model, for the purposes of intercomparison between models. Differences between the Methods 1 and 2 of Cess and Potter and a variant method are addressed. Method 1 is shown to be the least robust of all methods, due to the potential uncertainties related to persistent cloudiness, length of the sampling period and biases in retrieved clear-sky quantities due to insufficient sampling of the diurnal cycle. Method 2 is proposed as an unambiguous way to produce consistent radiative diagnostics for intercomparing model results. The impact of the three methods on the derived sensitivities and cloud feedbacks following an imposed change in sea surface temperature is discussed. The sensitivity of the results to horizontal resolution is considered by using the diagnostics from parallel integrations with T21 version of the model. DOE

MAGNETIC EARTH IONOSPHERE RESONANT FREQUENCIES (MEIRF) PROJECT Semiannual Progress Report, Sep. 1992 - Mar. 1993

Craig Spaniol Jun. 1993 69 p

(Grant NAG5-1267)

(NASA-CR-193182; NAS 1.26:193182) Avail: CASI HC A04/MF A01

The West Virginia State College Community College Division NASA Magnetic Earth Ionosphere Resonant Frequencies (MEIRF) study is described. During this contract period, the two most significant and professionally rewarding events were the presentation of the research activity at the Sir Isaac Newton Conference in St. Petersburg, Russia, and the second Day of Discovery Conference, focusing on economic recovery in West Virginia. An active antenna concept utilizing a signal feedback principle similar to regenerative receivers used in early radio was studied. The device has potential for ELF research and other commercial applications for improved signal reception. Finally, work continues to progress on the development of a prototype monitoring station. Signal monitoring, data display, and data storage are major areas of activity. In addition, we plan to continue our dissemination of research activity through presentations at seminars and other universities. CASI

DATA PROCESSING UNITS FOR EIGHT MAGNETOSPHERIC PARTICLE AND FIELD SENSORS

R. Koga, S. S. Immamoto, N. Katz, and S. D. Pinkerton 29 Jan. 1993 10 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F04701-88-C-0089)
(AD-A264403; TR-0091(6940-05)-05; SMC-TR-93-20) Avail: CASI HC A02

The DPUA, DPUB, and DPU57 data processing units associated with eight CRRES particle and field experiments are described. Operation of the experiments is controlled by the data processing units (DPU's), which constitute the interface between the spacecraft and the sensors subserving the individual experiments. All data to and from the sensors pass through the associated DPU's. Each DPU consists of a microprocessor, power supply, signal handler, and various peripherals such as input/output buffers and specialized data processing hardware. In addition to experiment control and data processing functions, DPU software performs such tasks as loading the system software from ROM into RAM, writing the memory-resident look-up tables utilized by the DPU hardware, checking the system RAM's for memory retention faults, outputting system memory to the telemetry stream, and outputting a fixed pattern of telemetry. To maximize the available telemetry bandwidth, much of the raw sensor data is analyzed by the DPU's, using various onboard processing schemes, and then compressed prior to being output in telemetry. LARGE EDDY SIMULATIONS OF THE ATMOSPHERIC BOUNDARY LAYER EAST OF THE COLORADO ROCKIES Ph.D. Thesis

Keeley Rochelle Costigan 1992 150 p
Avail: Univ. Microfilms Order No. DA9311367

Large eddy simulation, LES, has often been carried out for the idealized situation of a simple convective boundary layer. Studies of dual Doppler radar and aircraft data from the Phoenix 2 experiment indicate that the boundary layer of the Colorado High Plains is not a purely convective boundary layer and it is influenced by the mountains to the west. The purpose is to investigate the atmospheric boundary layer on one particular day on the Colorado High Plains. This research applies a LES nested within larger grids, which contain realistic topography and can simulate the larger-scale circulations initiated by the presence of the mountain barrier. How and to what extent the atmospheric boundary layer of the Colorado High Plains is influenced by larger scale circulations and other phenomena associated with the mountain barrier to the west is investigated. Comparison of the model produced fields and turbulence statistics to the observations of the Phoenix 2 experiment shows that the nested grid LES reproduces the characteristics of the atmosphere for the case study day reasonably well. Further comparison of the model results to other LES for a purely convective, horizontally homogeneous boundary layer indicates that the mountains influence the atmospheric boundary layer over the plains to the east in several ways. The mountains contribute to the vertical shear of the horizontal winds through the thermally-induced mountain-plains circulation. As a consequence of the wind shear, the boundary layer that develops over the mountains is advected eastward over the top of the plains boundary layer, which is developing separately. This layer is marked by a mixture of gravity waves and turbulence and is atypical of a purely convective boundary layer. Just below this layer, the capping inversion of the plains boundary layer is weak and poorly defined compared to the inversions capping purely convective boundary layers. Gravity waves, triggered by the obstacle of the Rocky Mountains and by convection in the mountain boundary layer, also influence the atmosphere above the Colorado High Plains. These influences are found to have significant effects on the turbulence statistics and the energy spectra. Dissert. Abstr.

THE IMPACT OF VEGETATION ON THE ATMOSPHERIC BOUNDARY LAYER AND CONVECTIVE STORMS Ph.D. Thesis

Tsengdar John Lee 1992 155 p
Avail: Univ. Microfilms Order No. DA9311386

The impact of vegetation on atmospheric boundary layer and convective storms is examined through the construction and testing of a soil-vegetation-atmosphere transfer (SVAT) model. The Land Ecosystem-Atmosphere (LEAF) model is developed using an elevated canopy structure, an above-canopy aerodynamic resistance, two in-canopy aerodynamic resistances, and one stomatal conductance functions. The air temperature and humidity are assumed to be constant in the canopy whereas the wind and radiation follow a specified vertical profile. A simple dump-bucket method is used to parameterize the interception of precipitation and a multi-layer soil model is utilized to handle the vertical transfer of soil water. Evaporation from soil and wet leaves and transpiration from dry leaves are evaluated separately. The solid water uptake is based on soil water potential rather than on the length of roots. Separate energy budgets for vegetation and for the soil are used in order to remove unnecessary assumptions on energy partition between the vegetation and the substrate. Primary parameters are LAI, maximum stomatal conductance, and albedo. Secondary parameters include displacement height and environmental controls on stomatal resistance function. Due to the complexity of the LEAF model, statistical methods are used to improve LEAF model performance. The Multi-response Randomized Bock Permutation (MRBP) procedure is used to guide the choice of model parameter values. The Fourier Amplitude Sensitivity Test (FAST) is applied to better understand the model behavior in response to the changes in model parameters. Finally, LEAF is used to study the growth of boundary layer and the local thermal circulations generated by surface inhomogeneities. Results show the atmospheric boundary layer is substantially cooler and more moist over unstressed vegetation than over bare dry soil. Thermally forced circulation can result from the juxtaposition of two vegetation types due to different biophysical characteristics. Results from three-dimensional simulations show that the surface spatial heterogeneities made by vegetation play an important role in generating local convective storms.

A MODEL FOR THE SUBDUCTION MECHANICS OF FLEXIBLE LITHOSPHERE AND ITS VISCOUS COUPLING TO THE MANTLE USING POWER-LAW RHEOLOGIES Ph.D. Thesis

David VanDyke Kemp 1992 266 p
Avail: Univ. Microfilms Order No. DA9310859

Plate subduction plays a fundamental role in mantle convection due to the localization of negative buoyancy and the plate's role as a stress guide. Convection studies have demonstrated subduction's dynamic significance, but the subduction mechanics of plates that have enhanced strength relative to the asthenosphere and self-consistently defined trajectories have not been previously investigated. In this study, I seek the steady-state plate profile which is consistent with loads acting on the plate and its rheological response; the plate profile is not prescribed a priori. The plate has a uniform, rate-dependent rheology, allowing continuous bending from the open ocean to a depth of 670 km. Loads acting to define the plate shape include body forces, static pressure anomalies, shear contact with the overriding plate, and dynamic pressures and shear stresses resulting from viscous coupling to the mantle. These loads are in turn coupled to the plate shape, with the mantle responses described by a power-law rheology. In addition, the slabs may meet resistance at the top of the lower mantle and may experience a depth-independent lateral pressure drop. Numerical experiments have been conducted using a combination of spectral methods and nonlinear optimization. The plate's flexural strength is found capable of making a significant contribution to slab support, allowing more shallow stable dips than previous corner-flow models. Dynamic pressures do not provide 'unbending stresses' to plates, however. Weak plates unbend beneath the forearc load and also downdip from the arc under their own weight. Stronger plates may not unbend at all without weakening as they subduct. Preferred models have trenches no deeper than 12.5 km and do not overturn in the upper mantle. Although one each is 40, 60 and 80-km thick, a constant in the moment/curvature relationship for these matches to within 20 percent. A factor of five variation would result from the thickness variation without compensating adjustment of the plate rheology. Support at depth may increase the dynamic pressures by making the mantle wedge more narrow, but does not appear to significantly alter the forearc shape, and thus the static pressures there. Modest depth-independent pressure drops across the weak slabs are capable of significantly decreasing their dip in the upper mantle and reducing the slab pull. Author

AN OVERVIEW OF INTERTROPICAL CONVERGENCE AND INTERTROPICAL DISCONTINUITY

E. C. Adibe Sep. 1992 27 p Limited Reproducibility: More than 20%

of this document may be affected by microfiche quality
(DE93-619229; IC-92/286) Avail: CASI HC A03 (US Sales Only)

In its simplest form, the general circulation of the atmosphere may be regarded as two meridional circulation in opposite directions and separated by what is sometimes known as the 'meteorological equator'. The meteorological equator, as a planetary entity, divides the troposphere into two meteorological hemispheres, ensuring energy equilibrium in them, and corresponding to what are known as intertropical convergence zone, intertropical discontinuity, intertropical front, monsoon front, etc. The meteorological equator moves from the south towards the north and then from the north towards the south in harmony with the apparent movement of the Sun. NASCAP PROGRAMMER'S REFERENCE MANUAL Final Report
M. J. Mandell, P. R. Stannard, and I. Katz May 1993 549 p
(Contract NAS3-22826; RTOP 506-41-52)
(NASA-CR-191044; E-7850; NAS 1.26:191044) Avail: CASI HC A23/MF A04

The NASA Charging Analyzer Program (NASCAP) is a computer program designed to model the electrostatic charging of complicated three-dimensional objects, both in a test tank and at geosynchronous altitudes. This document is a programmer's reference manual and user's guide. It is designed as a reference to experienced users of the code, as well as an introduction to its use for beginners. All of the many capabilities of NASCAP are covered in detail, together with examples of their use. These include the definition of objects, plasma environments, potential calculations, particle emission and detection simulations, and charging analysis. Author (revised)

FFTSCAN: A PROGRAM FOR SPECTRAL SMOOTHING USING FOURIER TRANSFORMS
W. O. Gallery and S. A. Clough 19 May 1992 24 p
(Contract F19628-89-C-0150)
(AD-A264921; PL-TR-92-2131; AD-E201529) Avail: CASI HC A03/MF A01

FFTSCAN is a computer program which uses Fourier Transforms to convolve a spectrum with an instrument spectral scanning function. This technique mimics the operation of Fourier transform spectroscopy and preserves the full extent of the scanning function, which is particularly important for functions with large side lobes, like sin(x)/x. Five scanning functions commonly used in Fourier transform spectroscopy are available: sinc, sinc2, Beer, Hamming, and Hanning, plus triangle and gauss. The program is specifically adapted to process spectra created by the atmospheric transmittance/radiance program FASCODE. A special, disk-based Fourier transform routine allows FFTSCAN to handle spectra of any size. FFTSCAN is more accurate and as, or more, efficient that the existing equivalent FASCODE routines. This report describes the mathematical basis for spectral smoothing in the Fourier domain and gives the user instructions for FFTSCAN. It gives examples of spectral smoothing, including estimates of error limits and computational times, and provides guidance on implementing the program on different computers. DTIC

RESULTS FROM A YEAR-LONG AURORAL-E MEASUREMENT CAMPAIGN
Robert B. Rose, R. D. Hunsucker, and Gus K. Lott Apr. 1993 8 p
(AD-A265059) Avail: CASI HC A02/MF A01

The Disturbance Impact Assessment System (DIAS) was developed to make qualitative assessments of the impact of solar flares on high latitude HF propagation. The system employed new techniques in expert system technology to describe some of the vaguer aspects in high latitude disturbance phenomenology. In developing the rulesets for the different high latitude disturbances, it was obvious that there was some confusion regarding the occurrence characteristics of sporadic-E, auroral sporadic-E, and just plain auroral-E. It was very difficult to determine the type of sporadic ionization being described in different studies. In order to gain better insight on the characteristics of auroral-E so an accurate ruleset for DIAS could be developed, it was decided to conduct a year-long measurement campaign. The results of the first year of measurements are described, theories on the generation of sporadic ionization at E-region ionospheric heights are presented, and finally an attempt to correlate the observations to the theories is made. A NEW DATA COLLECTION SYSTEM FOR IONOSPHERIC MODELLING AND RELATED TOPICS Final Report, 7 Nov. 1988 - 30 Sep. 1992
Robert E. Sheehan 15 Apr. 1993 100 p
(Contract F19628-89-K-0001)
(AD-A265893; PL-TR-92-2263) Avail: CASI HC A05/MF A02

Work performed under this contract can be divided into the following areas: (1) development and testing of a PC based Scintillation Data Recording System (SDRS) and related analysis software, (2) updating and extending D. Anderson's global ionospheric model for studies concerning the generation and transport of polar cap patches, and (3) implementation of existing and new software utilities on the PC and SUN workstation in support of Phillips Laboratory. Beginning in Nov. 1990, SDRS has been installed at 5 field sites from Thule, Greenland to Ascension Island in the South Atlantic. Modified systems have also become TEC receiving stations for a tomography project and a remote access system designed to report scintillation activity at field sites. New software was developed to extract and display SDRS and TEC phase data on the PC. Two important additions were made to the Anderson model; the Hardy statistical model describes electron precipitation patterns, and production caused by precipitating electrons is based on a parameterized version of Strickland's flux transport model provided by R. Daniel. DTIC

OBSERVING AND MODELLING F-REGION IONOSPHERIC DYNAMICS USING THE (O2) 7320A EMISSION Ph.D. Thesis
Stephen S. Carr 1992 330 p
(AD-A265407; AFIT/CI/CIA-92-031D) Avail: CASI HC A15/MF A03

Limb-scan observations of Doppler line profiles from the (OII) lambda 7320A emission at F-Region altitudes, made with the Fabry-Perot interferometer (FPI) on the Dynamics Explorer-2 (DE-2) spacecraft, have been analyzed to provide measurements of the meridional component of the ion convection velocity along the instrument line-of-sight. The DE-2 results presented here demonstrate the first spaceborne use of the remote-sensing Doppler techniques for measurements of ionospheric convection. The FPI meridional ion drift measurements have been compared with nearly simultaneous in situ ion drift measurements from the Retarding Potential Analyzer (RPA) on DE-2. Once allowance is made for the temporal lag between the in situ and remote measurements, the results from the two techniques are found to be in good agreement, within specified experimental errors, giving confidence in the FPI measurements. AN ATMOSPHERIC BOUNDARY LAYER STABILITY ESTIMATOR FOR URBAN AREAS Final Report
J. S. Scire and S. R. Hanna Dec. 1992 86 p
(Contract DAAD07-91-C-0135)
(AD-A265189; ARL-CR-10) Avail: CASI HC A05/MF A01

In most U.S. Army atmospheric dispersion models, the Pasquill methodology is used to estimate stability in the boundary layer. As a result, there are discontinuities in calculated dispersion among the six stability classes. Furthermore, corrections for surface conditions (i.e., fields, urban areas, or forests) are also discrete functions. Recent theoretical developments provide the basis for revising this methodology using principles of Monin-Obukhov and convective similarity theory. A model is described which predicts stability indicators in a continuous manner. The procedure consists of three components: a soil moisture module to predict surface moisture; a meteorological module, based on an energy balance method, to predict surface energy fluxes and boundary layer parameters; and a set of similarity relations to estimate atmospheric stability and plume dispersion parameters. The model is designed for PC use and requires only routinely available meteorological and land use data. DTIC

STUDIES OF DYNAMICAL PROCESSES AFFECTING THE DISTRIBUTION OF STRATOSPHERIC OZONE Final Report, 1 Jan. 1990 - 30 Jun. 1993
Kenneth P. Bowman (Illinois Univ., Urbana.) 27 Jul. 1993 3 p
(Grant NAGw-992)
(NASA-CR-193477; NAS 1.26:193477) Avail: CASI HC A01/MF A01

The purpose of the research was to understand large-scale tracer transport processes in the stratosphere. Two approaches were taken. The first is analysis of tracer observations, especially satellite observations of ozone concentration and total column ozone. The second is numerical simulation of tracer transport processes. Topics researched include: quasi-biennial oscillation (QBO) and stratospheric ozone; mixing in the polar vortices; polar stratospheric clouds (PSC) properties from Antarctic lidar data; and statistical methods for numerical experiments. POLAR MESOSPHERIC WAVES AND STRUCTURE Final Report
James C. Ulwick May 1993 18 p
(Contract N00014-91-J-1883)
(AD-A265360; SDL/93-039) Avail: CASI HC A03/MF A01

This report discusses a quantitative comparison of rocket observations of electron density fluctuations and simultaneous 53.5 MHz radar measurements that were obtained during the MAC/SINE campaign in Northern Norway. Two of the three rockets launched during the Turbulence/Gravity Wave salvo were flown during conditions that allowed a detailed investigation. A large part of the data from these rocket flights indicate that the radar reflectivity is about 10 dB enhanced over what would be expected from the rocket observations in the case of isotropic electron density fluctuations. The observations can be reconciled under the assumption of an anisotropic turbulence. Assuming a simple model spectrum for the electron density fluctuations, we derive a relation between the rocket and radar observation that covers the whole range from isotropic turbulent scatter to Fresnel-scatter at horizontal density stratifications. For the observed data set, an anisotropy which typically corresponds to a ratio of horizontal to the vertical coherence length of about 10 is consistent with the comparison of rocket and radar observations. A similar anisotropy is found in the observed aspect sensitivity of the radar echoes. The variation of the anisotropy with height and time shows an anticorrelation with the turbulence level of the mesosphere as deduced from the spectral width of the radar echoes. The anisotropy is found to maximize in heights where density displays deep 'bite-outs'. These depletion in the electron density were independently observed by a Langmuir and an admittance probe on board the rocket. DTIC

Progress to date in an ongoing study to analyze and model emissions leaving a proposed High Speed Civil Transport (HSCT) from when the exhaust gases leave the engine until they are deposited at atmospheric scales in the stratosphere is documented. A kinetic condensation model was implemented to predict heterogeneous condensation in the plume regime behind an HSCT flying in the lower stratosphere. Simulations were performed to illustrate the parametric dependence of contrail droplet growth on the exhaust condensation nuclei number density and size distribution. Model results indicate that the condensation of water vapor is strongly dependent on the number density of activated CN. Incorporation of estimates for dilution factors into a Lagrangian box model of the far-wake regime with scale-dependent diffusion indicates negligible decrease in ozone and enhancement of water concentrations of 6-13 times background, which decrease rapidly over 1-3 days. Radiative calculations indicate a net differential cooling rate of the plume about 3K/day at the beginning of the wake regime, with a total subsidence ranging between 0.4 and 1 km. Results from the Lagrangian plume model were used to estimate the effect of repeated superposition of aircraft plumes on the concentrations of water and NO(y) along a flight corridor. Results of laboratory studies of heterogeneous chemistry are also described. Kinetics of HCl, N2O5 and ClONO2 uptake on liquid sulfuric acid were measured as a function of composition and temperature. Refined measurements of the thermodynamics of nitric acid hydrates indicate that metastable dihydrate may play a role in the nucleation of more stable trihydrates PSC's. Author (revised)

ATMOSPHERIC AND SPECTROSCOPIC RESEARCH IN THE FAR INFRARED Final Technical Report, 23 Feb. 1989 - 22 Feb. 1992
Kwangjai Park and James V. Radostitz 1992 6 p
(Grant NAG1-963)
(NASA-CR-193551; NAS 1.26:193551) Avail: CASI HC A02/MF A01

The University of Oregon (UO) has been a major participant in the development of far infrared spectroscopic research of the stratosphere for the purpose of understanding the ozone layer processes. The UO has had a 15-year collaboration with the Italian group of B. Carli, and have participated in the 1978/79 Sub-millimeter Infrared Balloon Experiment (SIBEX), in the Balloon Intercomparison Campaign, (BIC), in the Infrared Balloon Experiment (IBEX), and in the recently concluded Far Infrared Experiment for UARS Correlative Measurements (FIREX). Both IBEX and FIREX programs were conducted in collaboration with NASA Langley, and were designed as validation flights in support of the Upper Atmosphere Research Satellite (UARS) Program. The technique of atmospheric far infrared spectroscopy offers two important advantages. First, many chemically important species can be measured simultaneously and co-spatially in the atmosphere. Second, far infrared atmospheric spectra can be obtained in thermal emission without reference to the sun's position, enabling full diurnal and global coverage. Recent improvements in instrumentation, field measurements, and molecular concentration retrieval techniques are now making the far infrared a mature measurement technology. This work to date has largely focused on balloon-based studies, but the future efforts will focus also on satellite-based experiments. A program of research in the following general areas was proposed: Laboratory Pressure broadening coefficient studies; specialized detector system assembly and testing; and consultation and assistance with instrument and field support. The proposal was approved and a three-year research grant titled 'Atmospheric and Spectroscopic Research in the Far Infrared' was awarded. A summary of technical accomplishments attained during the grant period are presented. Author (revised)

MID-LATITUDE IONOSPHERIC RESPONSE TO ACTIVE EXPERIMENTS Final Report, 1 May 1990 - 30 Apr. 1992
John C. Foster 1992 5 p
(Grant NAG5-669)
(NASA-CR-193549; NAS 1.26:193549) Avail: CASI HC A01/MF A01

Understanding the ion chemistry and conditions leading to the formation of ionospheric depletions (ionospheric holes) was an important objective of the NASA active ionospheric experiment program. Millstone Hill radar observations were used to monitor the magnitude and temporal extent of the plasma holes produced under varying conditions. The major objective of the completed project was to provide radar diagnostic support for individual NASA rocket campaigns flown from Wallops Island. Two rocket programs, NICARE and REDAIR 2, were selected by NASA for radar support during the proposal period and pre-launch and in-flight radar observations were provided for each as well as basic reduction of the acquired data for scientific analysis. Radar operations and analysis for both of these experiments were performed as proposed and the work on these projects at M.I.T. was completed. Author (revised)

THE CLOUD RADIATIVE FEEDBACK OF A MIDLATITUDE SQUALL LINE SYSTEM AND IMPLICATION FOR CLIMATE STUDY
H. N. S. Chin 1 May 1992 12 p Presented at the 11th International Conference on Clouds and Precipitation, Montreal, Ontario, 17-21 Aug. 1992
(Contract W-7405-eng-48)
(DE93-010511; UCRL-JC-110400; CONF-920881-2) Avail: CASI HC A03/MF A01

The main objectives of this study are as follows: (1) to study the impact of longwave and shortwave radiation on the thermodynamic and kinematic structure of a midlatitude squall line; and (2) to explore the influence of specifically including the ice phase in the cloud-radiation feedback mechanism for climate models. LEE WAVES: BENIGN AND MALIGNANT
M. G. Wurtele, A. Datta, and R. D. Sharman Jun. 1993 30 p Sponsored by NASA. Dryden Flight Research Facility
(Contract NCC2-0374; RTOP 505-68-50)
(NASA-CR-186024; H-1890; NAS 1.26:186024) Avail: CASI HC A03/MF A01

The flow of an incompressible fluid over an obstacle will produce an oscillation in which buoyancy is the restoring force, called a gravity wave. For disturbances of this scale, the atmosphere may be treated as dynamically incompressible, even though there exists a mean static upward density gradient. Even in the linear approximation - i.e., for small disturbances - this model explains a great many of the flow phenomena observed in the lee of mountains. However, nonlinearities do arise importantly, in three ways: (1) through amplification due to the decrease of mean density with height; (2) through the large (scaled) size of the obstacle, such as a mountain range; and (3) from dynamically singular levels in the fluid field. These effects produce a complicated array of phenomena - large departure of the streamlines from their equilibrium levels, high winds, generation of small scales, turbulence, etc. - that present hazards to aircraft and to lee surface areas. The nonlinear disturbances also interact with the larger-scale flow in such a manner as to impact global weather forecasts and the climatological momentum balance. If there is no dynamic barrier, these waves can penetrate vertically into the middle atmosphere (30-100 km), where recent observations show them to be of a length scale that must involve the coriolis force in any modeling. At these altitudes, the amplitude of the waves is very large, and the phenomena associated with these wave dynamics are being studied with a view to their potential impact on high performance aircraft, including the projected National Aerospace Plane (NASP). The presentation shows the results of analysis and of state-of-the-art numerical simulations, validated where possible by observational data, and illustrated with photographs from nature. Author (revised)

The ECMWF global model is used to simulate the climate from 1979 to 1988. This integration is in support of the WGNE Atmospheric Model Intercomparison Project (AMIP). The model uses the observed monthly sea surface temperature for the ten year period during the integration. Anomaly correlation and RMS calculations are carried out between monthly mean observed circulation and the model results, although the use of monthly mean data restricts the conclusions to the low frequency variability. The variables and regions considered are the 500 hPa geopotential and MSU temperatures for the Northern Hemisphere (30N to 70N), the 200 hPa zonal wind and MSU temperatures for the equatorial belt (15S to 15N), and the 1000 hPa zonal wind for the equatorial Pacific (15N to 15S and 120E to 100W). The results show: (1) For the midlatitude 500 hPa geopotential there is a signal in the model results for the ENSO events of 1982/1983 and 1986/1987; (2) the model underestimates the midlatitude 500 hPa geopotential interannual variability as measured by the RMS but overestimates the MSU temperature variability in this region; (3) in general, outside of the ENSO periods, there is little correlation between the model and observed data anomalies of midlatitude 500 hPa geopotential; (4) in the tropics the variables evince a stronger correlation with observations, with the 200 hPa winds yielding greater agreement than the MSU temperatures and the 1000 hPa zonal wind showing a significant correlation with observations in the interannual variation; (5) in the tropics the model underestimates the variability of the 200 hPa wind and MSU temperature; (6) the model, although non-interacting with the ocean, produces a credible simulation of the low frequency variability of the equatorial JPacific low level zonal wind. ON THE IMPORTANCE OF MESOSCALE POTENTIAL VORTICITY ANOMALIES AND TOPOGRAPHIC FORCING DURING CYCLONE REDEVELOPMENT ACROSS THE APPALACHIANS: A GALE CASE STUDY Ph.D. Thesis

Christopher OHandley 1992 446 p

Avail: Univ. Microfilms Order No. DA9311872

The evolution of the structure of cyclones and cold fronts over the eastern United States is investigated observationally. Two primary goals of the research are to understand the mechanisms controlling cyclone and frontal evolution across the Appalachian mountains, and to document the presence and importance of mesoscale disturbances during cyclogenesis. The research was accomplished in two phases. First, a climatological survey of seven winter seasons of cyclones and fronts was performed. This study revealed that cold fronts are slowed and deformed by the Appalachians, with the cross-frontal pressure and thermal contrasts enhanced considerably across the mountains. In addition, cyclones generally curve northward and dissipate over the mountains while secondary development occurs further south over the lee region. Both upper-level 'forcing' and lower-level thermal structure are important in determining the exact location of redevelopment. Second, a detailed case study was conducted of a cyclone observed during the Genesis of Atlantic Lows Experiment (GALE). The primary cyclone dissipated over the northern Appalachians while a secondary lower tropospheric (800-900 mb) cyclone formed over eastern North Carolina. However, strong low-level static stability prevented this disturbance from penetrating to the surface. Instead, cyclogenesis occurred offshore when two mesoscale mid-tropospheric (500 mb) PV maxima, one of which represented an upper level frontal zone, moved over a series of quasi-stationary shallow cloud clusters over the Gulf Stream. Meanwhile, the primary surface cold front was blocked west of the Appalachians, but the mid-level (700-850 mb) front progressed unimpeded across the mountains. Later, a new surface front formed east of the mountains through diabatic processes. Both surface heating and evaporation played important roles in the frontal redevelopment. These results indicate that future mesoscale models will need to incorporate topography and diabatic processes with increased accuracy. In addition, observing and analysis systems must be capable of resolving mesoscale disturbances of the type identified here. Further research is suggested to determine the prevalence of such features, their impact on cyclogenesis, and the degree of resolution required for successful prediction. Author

SELECTED UPPER-AIR WIND SPEED DISTRIBUTIONS Final Report

Elton P. Avara Dec. 1992 106 p

(AD-A264822; ARL-TR-38) Avail: CASI HC A06/MF A02

Some weapon systems are sensitive to winds in the lower part of the atmosphere. Wind speed distributions and random wind speeds derived from the distributions are often required to help determine the operational capabilities of these systems. A literature survey revealed that investigators usually used either a log-normal or a Weibull distribution as the model for the distribution of wind speeds independent of direction. In addition to these two distributions, a gamma distribution is also evaluated in this report. Wind speeds observed in three different geographical regions at 10 altitudes up to 5 km 3 diurnal time periods, and 5 seasonal time periods were evaluated. This report contains the results of the wind speed analysis for some of the combinations of altitude, diurnal time periods, and seasonal time periods for each of the three geographical regions--European Lowlands, European Highlands, and Mideast Desert. The observed wind speed distributions were adequately represented by the analytical distributions. DTIC

DESIGN OF A GLOBAL SOIL MOISTURE INITIALIZATION PROCEDURE FOR THE SIMPLE BIOSPHERE MODEL

G. E. Liston (Universities Space Research Association, Columbia, MD.), Y. C. Sud, and G. K. Walker (General Sciences Corp., Laurel, MD.) Aug. 1993 130 p

(RTOP 039-09-01-25)

(NASA-TM-104590; NAS 1.15:104590; Rept-93B00092) Avail: CASI HC A07/MF A02

Global soil moisture and land-surface evapotranspiration fields are computed using an analysis scheme based on the Simple Biosphere (SiB) soil-vegetation-atmosphere interaction model. The scheme is driven with observed precipitation, and potential evapotranspiration, where the potential evapotranspiration is computed following the surface air temperature-potential evapotranspiration regression of Thomthwaite (1948). The observed surface air temperature is corrected to reflect potential (zero soil moisture stress) conditions by letting the ratio of actual transpiration to potential transpiration be a function of normalized difference vegetation index (NDVI). Soil moisture, evapotranspiration, and runoff data are generated on a daily basis for a 10-year period, January 1979 through December 1988, using observed precipitation gridded at a 4 deg by 5 deg resolution. THE AIR FORCE INTERACTIVE METEOROLOGICAL SYSTEM: A RESEARCH TOOL FOR SATELLITE METEOROLOGY

Charles F. Ivaldi, Jr., Gary B. Gustafson, and Joseph Doherty 2 Dec.

1992 92 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F19628-91-C-0011)
(AD-A265957; PL-TR-92-2327; SR-2) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report summarizes work that was performed under a research contract with the Satellite Meteorology Branch of the Phillips Laboratory (Geophysics Directorate) Atmospheric Sciences Division. The topic addressed is the use of the Air Force Interactive Meteorological System (AIMS) as a research tool for the acquisition, processing, display, and management of large sets of satellite data obtained from different platforms and sensors. Of particular importance is the foundation that AIMS provides for establishing an optimal satellite data processing system based on a systematic and integrated approach to data handling and manipulation. This foundation is composed of three functional areas: (1) access to meteorological data sources including--direct broadcast NOAA, DMSP, and GOES satellite data, global surface and upper air reports from the NWS Family of Services, and lightning data from the SUNY-Albany lightning detection network; (2) data visualization and processing that employs both 8-bit and 24-bit full color imaging workstations; and (3) interactive development, data analysis, and batch processing capabilities supported by mid-range performance minicomputers. This report includes a historical perspective of AIMS, its current configuration, a review of scientific applications supported by AIMS, ongoing work to provide an integrated approach to data management, analysis and processing, and a discussion of current short term needs and long range planning issues. UPDATED FORECAST OF ATLANTIC SEASONAL HURRICANE ACTIVITY FOR 1993

William M. Gray 5 Aug. 1993 16 p
Avail: CASI HC A03/MF A01

Details of the author's updated forecast of tropical cyclone activity for the Atlantic Ocean region including the Caribbean Sea and the Gulf of Mexico during 1993 are presented. This updated forecast utilizes meteorological data for June and July and is based on the author and his research colleagues ongoing research activities which relates the amount of seasonal Atlantic tropical cyclone activity to five factors: namely, (1) three measures of the Quasi-Biennial Oscillation of equatorial stratospheric zonal wind (QBO) at 50 mb (20 km) and 30 mb (23 km) and the absolute value of the shear between these levels; (2) the El Nino Southern Oscillation (ENSO) conditions as specified by the Equatorial East Pacific Sea Surface Temperature Anomaly (SSTA) and the value of the Tahiti minus Darwin surface pressure; (3) Caribbean basin Sea-Level Pressure Anomalies (SLPA) and upper tropospheric 200 mb Zonal Wind Anomalies (ZWA); (4) two measures of West African Rainfall (AR) anomalies, one of June-July in the Western Sahel region, and the other the previous year Aug. through Nov. precipitation in the Gulf of Guinea region; and (5) the surface west to east pressure and temperature gradients across the Western Sahel region of Africa during Feb. through May. Information received by the author through 4 Aug. 1993 indicates that the 1993 hurricane season should, overall be about an average season when compared with hurricane activity of the last 43 years. Our statistical analysis indicates that this season should have about 6 hurricanes, 10 named storms of at least tropical storm intensity, about 25 hurricane days, a total of 50 named storm days and a Hurricane Destruction Potential of 55. Because the Western Sahel is expected to again have below average rainfall this year, it is anticipated that there will be only two intense or major hurricanes of Saffir/Simpson intensity category 3, 4, or 5 this season. This updated forecast is for slightly calmer conditions than were suggested in the 24 Nov. 1992 and 4 Jun. 1993 forecasts for 1993. A verification of this forecast will be issued in late Nov. [ACTIVITIES RELATING TO UNDERSTANDING THE INITIATION, ORGANIZATION AND STRUCTURE OF MOIST CONVECTION IN THE SOUTHEAST ENVIRONMENT] Final Report

Richard T. McNider 18 Jun. 1992 251 p
(Contract NAS8-36479)
(NASA-CR-193829; NAS 1.26:193829) Avail: CASI HC A12/MF A03

In the spring and summer of 1986, NASA/Marshall Space Flight Center (MSFC) will sponsor the Satellite Precipitation And Cloud Experiment (SPACE) to be conducted in the Central Tennessee, Northern Alabama, and Northeastern Mississippi area. The field program will incorporate high altitude flight experiments associated with meteorological remote sensor development for future space flight, and an investigation of precipitation processes associated with mesoscale and small convective systems. In addition to SPACE, the MIcroburst and Severe Thunderstorm (MIST) program, sponsored by the National Science Foundation (NSF), and the FAA-Lincoln Laboratory Operational Weather Study (FLOWS), sponsored by the Federal Aviation Administration (FAA), will take place concurrently within the SPACE experiment area. All three programs (under the joint acronym COHMEX (COoperative Huntsville Meteorological EXperiment)) will provide a data base for detailed analysis of mesoscale convective systems while providing ground truth comparisons for remote sensor evaluation. The purpose of this document is to outline the experiment design criteria for SPACE, and describe the special observing facilities and data sets that will be available under the COHMEX joint program. In addition to the planning of SPACE-COHMEX, this document covers three other parts of the program. The field program observations' main activity was the operation of an upper air rawinsonde network to provide ground truth for aircraft and spacecraft observations. Another part of the COHMEX program involved using boundary layer mesoscale models to study and simulate the initiation and organization of moist convection due to mesoscale thermal and mechanical circulations. The last part of the program was the collection, archival and distribution of the resulting COHMEX-SPACE data sets. Derived from text

DEVELOPMENT OF A GRAPHICAL USER INTERFACE AND GRAPHICS DISPLAY FOR THE WIND SYSTEM

B. L. OSteen, J. D. Fast, and B. S. Suire 1992 13 p
(Contract DE-AC09-89SR-18035)
(DE93-011780; WSRC-RP-92-1425) Avail: CASI HC A03/MF A01

An advanced graphical user interface (GUI) and improved graphics for transport calculations have been developed for the Weather Information and Display System (WINDS). Two WINDS transport codes, Area Evac and 2DPUF, have been ported from their original VAX/VMS environment to a UNIX operating system and reconfigured to take advantage of the new graphics capability. A developmental prototype of this software is now available on a UNIX based IBM 340 workstation in the Dose Assessment Center (DAC). Automatic transfer of meteorological data from the WINDS VAX computers to the IBM workstation in the DAC has been implemented. This includes both regional National Weather Service (NWS) data and SRS tower data. The above developments fulfill a FY-93 DOE milestone. DOE

(Contract DE-AC09-89SR-18035)
(DE93-010381; WSRC-RP-93-778) Avail: CASI HC A04/MF A01

Atmospheric transport and diffusion models have been developed by the Environmental Technology Section (ETS) of the Savannah River Technology Center to calculate the location and concentration of toxic or radioactive materials during an accidental release at the Savannah River Site (SRS). The output from these models has been used to support initial on-site and off-site emergency response activities such as protective action decision making and field monitoring coordination. These atmospheric transport and diffusion models have been incorporated into an automated computer-based system called the (Weather Information and Display) System and linked to real-time meteorological and radiological monitoring instruments to provide timely information for these emergency response activities. This report documents various aspects of the WIND system. DOE

MODELING PRESENT AND FUTURE RIVER RUNOFF USING GLOBAL ATMOSPHERIC MODELS M.S. Thesis

Scott C. VanBlarcum Oct. 1992 120 p
(AD-A265274; AFIT/CI/CIA-92115) Avail: CASI HC A06/MF A02

A global atmospheric model is used to calculate the monthly river runoff for 30 of the world's major rivers for the present climate and for a doubled CO2 climate. The model has a horizontal resolution of 4 deg X 5 deg, but the runoff from each model box is quartered and added to the appropriate river drainage basin on a 2 deg X 2.5 deg resolution. A new routing scheme is used to allow runoff calculated for a particular grid box to flow to an adjacent downstream grid box and ultimately to the mouth of the river. The total instantaneous runoff leads runoff at the mouth by one to two months. The model generated runoff at the mouth is compared to observations for several different simulations. The runoff peaks of high-latitude rivers are due to spring snow melt and there is a time lag between when the snow melts and when the melt water reaches the mouth. The new routing scheme allows the calculation of runoff at any location in the river basin. Model-generated river runoff and precipitation for the Mississippi River and its tributaries are analyzed for the present climate, where annual precipitation is within 5% of the observed precipitation. However, model-generated monthly precipitation is too high in the spring and too low in the summer and fall. In a model simulation with doubled CO2, river runoff increases for 27 of the 30 rivers and in most cases coincides with increased precipitation. All high-latitude rivers show an increase in precipitation and runoff with a shift in the runoff maximum, approximately one month earlier, due to an earlier snow melt season. In a doubled CO2 climate, snow mass decreases for mid and high-latitude rivers in North America and northwestern Asia, but increases for rivers in northeastern Asia, where observed winter temperatures average -30 to -50 C. RAINFALL-RUNOFF ESTIMATION USING DIGITAL RADAR M.S. Thesis
Russell A. Kutzman 1992 119 p
(AD-A265390; AFIT/CI/CIA-92-114) Avail: CASI HC A06/MF A02

Storm runoff is a critical concern to meteorologists and hydrological forecasters. A runoff algorithm, part of a series of tropical weather algorithms developed for the NEXRAD (Next Generation Weather Radar) radar system, is presented. The algorithm is based on the relationship between the rainfall over the basin and the discharge response at the gauge station. The algorithm is designed to provide runoff as a function of time for a given input(s) of rainfall. With known overflow levels, flood potential can also be evaluated. The runoff algorithm examined outflow at five basins within the operating scope of the Pittsburgh National Weather Service (NES) radar. A comparison of the observed runoff was made with the algorithm generated discharge. In general, hydrograph accuracies improved with increasing rainfall excess. DTIC

AN EXAMINATION OF THE EVOLUTION OF RADIATION AND ADVECTION FOGS Final Report
Montie M. Orgill Jan. 1993 71 p
(Contract DAAD07-89-C-0035)
(AD-A266127; ARL-CR-24) Avail: CASI HC A04/MF A01

A literature study was done on radiation and advection fog evolution. For radiation fog, six stages of fog evolution have been identified -- (1) precursor, (2) sunset, (3) conditioning, (4) mature, (5) sunrise, and (6) dissipation. The evolution of advection fog models has been in parallel with radiation fog models, but no identified stages in the evolution of advection fog have been proposed: (1) precursor, (2) initiation, (3) mature, and (4) dissipation. Radiation and advection fog models will require greater sophistication in order to study fog spatial and temporal variability. Physical aspects that require further study are discussed. DTIC

A STUDY OF THE MERRITT ISLAND, FLORIDA SEA BREEZE FLOW REGIMES AND THEIR EFFECT ON SURFACE HEAT AND MOISTURE FLUXES
M. T. Rubes, H. J. Cooper, and E. A. Smith Washington Jul. 1993 154 p
(Grant NAG8-916)
(NASA-CR-4537; M-727; NAS 1.26:4537) Avail: CASI HC A08/MF A02

Data collected during the Convective and Precipitation/Electrification Experiment were analyzed as part of an investigation of the sea breeze in the vicinity of Merritt Island, Florida. Analysis of near-surface divergence fields shows that the classical 24-hour oscillation in divergence over the island due to the direct sea breeze circulation is frequently disrupted and exhibits two distinct modes: the classical sea breeze pattern and deviations from that pattern. A comparison of clear day surface energy fluxes with fluxes on other days indicates that changes in magnitudes were dominated by the presence or absence of clouds. Non-classical sea breeze days tended to lose more available energy in the morning than classical sea breeze days due to earlier development of small cumulus over the island. A composite storm of surface winds, surface energy fluxes, rainfall, and satellite visible data was constructed. A spectral transmittance over the visible wavelengths for the cloud cover resulting from the composite storm was calculated. It is shown that pre-storm transmittances of 0.8 fall to values near 0.1 as the downdraft moves directly over the site. It is also found that under post-composite storm conditions of continuous clear sky days, 3.5 days are required to evaporate back into the atmosphere the latent heat energy lost to the surface by rainfall. The Sandia Ocean Modeling System (SOMS) is not just one model but a modeling methodology to be applied in different modes (coarse or high resolution, boundary layers, with or without realistic topography, in a forecast or phenomenological mode, etc.) according to application requirements, hence its description as a modeling system. SOMS is applicable to a large range of geophysical flows from small lakes to large ocean basins. This document includes a description of governing equations and numerical methods and full details of the coding. Appendix A provides a complete listing of SOMS, including its movie-making modules. Appendix B presents the variables that appear in common blocks; this information is essential for a programmer intending to change the problem dimensions. Appendix C presents the results of a physical parameter sensitivity study. Appendix D presents results of a real ocean calculation. DOE

PRELIMINARY RESULTS OF THE COMPARISON OF ATSR MEASUREMENTS WITH IN SITU SEA TEMPERATURES
P. J. Minnett 17 Mar. 1993 42 p Presented at the Along Track Scanning Radiometer (ATSR) Science Team Meeting, Abingdon, England, 30 Mar. 1993
(Contract DE-AC02-76CH-00016)
(DE93-013399; BNL-48858; CONF-9303167-1) Avail: CASI HC A03/MF A01

During Oct. and Nov. 1991, the NATO Research Vessel Alliance sailed from Amsterdam into the western Mediterranean Sea, and measurements were made for the validation of ATSR data. This document reports the initial comparison between ATSR measurements and sea-surface temperatures (SST's) taken along the ship's track by an in situ thermometer at a depth of about 3m. DOE

STUDY OF THE SURFACE CIRCULATION TO THE NORTH OF BRANSFIELD STRAIT, ANTARCTICA M.S. Thesis [ESTUDO DA CIRCULACAO SUPERFICIAL AO NORTE DO ESTREITO DE BRANSFIELD, ANTARTICA]
Ronald BussdeSouza Nov. 1992 183 p In PORTUGESE
(INPE-5472-TDI/503) Avail: CASI HC A09/MF A02

A study of the meso-scale circulation to the North of Bransfield Strait, Antarctica (61-62 degrees S, 52.5-58.5 degrees W), utilizing the displacement trajectory of a Brazilian drifting buoy, tracked by NOAA 10 and 11 satellites during 01/26-02/21/89, is presented. Buoy positional data, together with in situ oceanographic and meteorological data, were used to obtain a detailed description of the surface current. With a mean velocity of 7.5 cm/s, and a highly zonal direction (89 degrees), the current derived from the buoy trajectory was, in great part, forced by the winds, in agreement with the Ekman model. The Ekman currents were computed for 0 and 10 meter depths, obtaining 21 and 8. 5 cm/s toward 108 degrees and 25 degrees, respectively. The regional geostrophic circulation for the surface and 10 meter levels disagreed with the circulation pattern measured by the buoy. The mean geostrophic currents at those levels were about 2 cm/s to the North. Analyzing the Total, Mean, and the Eddy Kinetic Energies (EKT, EKM and EKE, respectively), it was found that time-variable fluctuations measured by EKE comprised 91.7 percent of the EKT. In 2 absolute values, EKM and EKE were equal to 28.1 sq cm/s(exp 2) and 357.4 sq cm/s(exp 2), respectively. With the use of auto-correlational analysis, it was determined that the displacement series of the buoy's trajectory contain dominant zonal and meridional component periods of 21.7 and 11.5 days, respectively. Using the Maximum Entropy Method (MEM) of spectral analysis, it was determined that 75.9 percent of total zonal energy was related to periods of 14.9 to 37.7 days. For the meridional component of the residual displacement series, 66.2 percent of the energy was related to periods between 11.5 and 21.2 days. The MEM analysis also shows that periods of 4-5 days and 1 day (tidal) were important in both displacement series. Comparison of the periods obtained from MEM for buoy and atmospheric pressure time series measured at the Brazilian Antarctic Station, showed that the atmospheric forcing was responsible for the 25.5, 11-12, and 5-6 days oscillations in the current. Cross-correlational analysis of buoy displacement and atmospheric pressure series shows that the currents follow the atmospheric forcing with a lag of 14 days. This period seems to be related to large-scale variation in the atmospheric system. Displacement loops present in the buoy's trajectory are shown to be caused by diurnal tides, the most important tidal component in the study region. The appearance of these loops in the buoy's trajectory was related to the presence of an oceanic front, localized in the western part of the study area. A second front to the East, formed by the justaposition of water influenced by the Bellingshausen Sea and the more cold and saline water from the Weddell Sea, resulted in a current that caused a strong southward deflection of the buoy. The utilization of the ARGOS compatible Brazilian drifting buoy is shown to be an efficient tool in meso-scale studies, offering the possibility of delineating oceanic fronts, fluxes of water masses with known characteristics, and atmospheric and tidal influences on the surface currents. Results of studies like this one can be used as support to more complex studies in the areas of air-sea interaction, climatology, and distribution of planctonic organisms of economic interest, for example. ATMOSPHERIC CORRECTION OF AVIRIS DATA IN OCEAN WATERS Final Report
Gregory Terrie and Robert Arnone Jun. 1992 5 p
(AD-A264931; NRLD-PR92-075-352) Avail: CASI HC A01/MF A01

Hyperspectral data offers unique capabilities for characterizing the ocean environment. The spectral characterization of the composition of ocean waters can be organized into biological and terrigenous components. Biological photosynthetic pigments in ocean waters have unique spectral ocean color signatures which can be associated with different biological species. Additionally, suspended sediment has different scattering coefficients which result in ocean color signatures. Measuring the spatial distributions of these components in the maritime environments provides important tools for understanding and monitoring the ocean environment. These tools have significant applications in pollution, carbon cycle, current and water mass detection, location of fronts and eddies, sewage discharge and fate etc. DTIC

ACOUSTICS OF BUBBLY SEDIMENTS Final Report
A. Bedford and J. A. Hawkins 1 Apr. 1993 118 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1809)
(AD-A263726) Avail: Issuing Activity: Defense Technical Information Center (DTIC))

The generation and detection of sound in the ocean is important in military applications, in biological research, and in the geoacoustic profiling of the ocean bottom and the underlying sediments. Although the free propagation of sound through seawater is an important area of underwater acoustics, the interaction of sound waves with the sea floor frequently must be accounted for. In particular, using remote acoustic measurements to obtain seismic profiles of the ocean bottom depend on a good understanding of the reflection of sound from the water-sediment interface and the sound absorption characteristics of the sediment below the interface. A simple model for the sediment is a compressible fluid. The reflection coefficient can then be calculated from the impedance of the fluid. This simple model can be improved by including viscosity in the model. DTIC

NORMAL MODES OF THE WORLD'S OCEANS: A NUMERICAL INVESTIGATION USING PROUDMAN FUNCTIONS
Braulio V. Sanchez and Dennis Morrow (Cray Research, Inc., Beltsville, MD.) May 1993 40 p
(RTOP 926-00-00)
(NASA-TM-104587; Rept-93B00078; NAS 1.15:104587) Avail: CASI HC A03/MF A01

The numerical modeling of the normal modes of the global oceans is addressed. The results of such modeling could be expected to serve as a guide in the analysis of observations and measurements intended to detect these modes. The numerical computation of normal modes of the global oceans is a field in which several investigations have obtained results during the past 15 years. The results seem to be model-dependent to an unsatisfactory extent. Some modeling areas, such as higher resolution of the bathymetry, inclusion of self-attraction and loading, the role of the Arctic Ocean, and systematic testing by means of diagnostic models are addressed. The results show that the present state of the art is such that a final solution to the normal mode problem still lies in the future. The numerical experiments show where some of the difficulties are and give some insight as to how to proceed in the future. Author (revised)

NEAR SURFACE OCEAN PROCESSES: ACOUSTICAL OBSERVATIONS, AMBIENT SOUND, AND LANGMUIR CIRCULATION Ph.D. Thesis
Len Zedel 1991 259 p
Avail: Univ. Microfilms Order No. DANN72696

A study of near surface ocean processes based on observations made with an instrument incorporating both active and passive acoustical systems is described. The topics addressed include the organization of bubble clouds by Langmuir circulation, the modulation of ambient sound levels by surface wave action, and the interactions of vortices associated with Langmuir circulation. Observations in a deep ocean environment reveal bubble clouds organized into plumes of 100 m length and widths of about 5 m aligned with the wind through the action of Langmuir circulation. The depth of these plumes varies somewhat with wind speed with the greatest depths of 12 m occurring at wind speeds of 13 m/s. Using acoustic Doppler techniques, downward vertical velocities of 0.06 m/s are observed at 8 m depth within the bubble plumes. Ambient sound observations at 8 kHz are used to search for possible relationships between wave breaking and Langmuir circulation: no systematic relationship is identified. This investigation does reveal the occurrence of modulations to ambient sound levels in phase with the long (approximately 150 m) surface waves passing over the instrumentation (positioned at 30 m depth). A model of sound generation at the ocean surface suggests that individual sources must have spacings of less than 6 m to reproduce the observations. Increased breaking activity (or greater source levels) are required at long wave crests to explain these modulations: it could be caused either by interactions between long and short waves, or variations in wind stress over the long waves. The observations of Langmuir circulation reveal many coexisting scales of spacing between the wind rows. A mechanism capable of generating small scale vorticity of the appropriate orientation through wave breaking and vortex stretching is developed. The consequences of interactions between this small scale, two dimensional vorticity is then explored using a Lagrangian vorticity model. This model demonstrates that continuous injection of small scale vorticity close to the ocean surface can lead to circulation similar to that expected for Langmuir circulation: a distribution of circulations cell sizes results, down welling speeds exceed upwelling speeds, and the cell spacing scales vary in proportion to the depth at which a bottom boundary is placed in the model. Dissert. Abstr.

THE SUBDUCTION EXPERIMENT. CRUISE REPORT, R/V OCEANUS, CRUISE NUMBER 250 LEGS 1 AND 2. SUBDUCTION 2 MOORING DEPLOYMENT AND RECOVERY CRUISE, 25 JANUARY-26 FEBRUARY 1992 Technical Report, 25 Jan. - 26 Feb. 1992
Richard P. Trask, Nancy J. Brink, Lloyd Regier, and Neil McPhee Mar. 1993 106 p
(Contract N00014-90-J-1490)
(AD-A264922; WHOI-93-13; UOP-TR-93-2) Avail: CASI HC A06/MF A02

Subduction is the mechanism by which water masses formed in the mixed layer and near the surface of the ocean find their way into the upper thermocline. The subduction process and its underlying mechanisms were studied through a combination of Eulerian and Langrangian measurements of velocity, measurements of tracer distributions and hydrographic properties, and modeling. An array of five surface moorings carrying meteorological and oceanographic instrumentation were deployed for a period of two years beginning in June 1991 as part of an Office of Naval Research (ONR) funded Subduction experiment. Three eight month deployments were planned. The initial deployment of five surface moorings took place during the third leg of R/V Oceanus cruise number 240. The moorings were deployed at 18 deg N 34 deg W, 18 deg N 22 deg W, 25.5 deg N 29 deg W, 33 deg N 22 deg W, and 33 deg N 34 deg W. A Vector Averaging Wind Recorder (VAWR) and an Improved Meteorological Recorder (IMET) collected wind speed and wind direction, sea surface temperature, air temperature, short wave radiation, barometric pressure, and relative humidity. The IMET also measured precipitation. The moorings were heavily instrumented below the surface with Vector Measuring Current Meters (VMCM) and single point temperature recorders. Expendable bathythermograph (XBT) data were collected and meteorological observations were made while transiting between mooring locations. This report describes the work that took place during R/V Oceanus cruise 250 which was the second scheduled Subduction mooring cruise. During this cruise the first setting of the moorings were recovered and redeployed for a second eight month period. DTIC

REAL-TIME TOMOGRAPHY MOORING
James Lynch, Daniel Frye, Kenneth Peal, Stephen Liberatore, and Sean Kery Jun. 1992 144 p
(Contract N00014-C-90-0098)
(AD-A264923; WHOI-92-29) Avail: CASI HC A07/MF A02

A real-time tomography system has been developed which combines ocean acoustic tomography with satellite-based time keeping and satellite telemetry. The basis of the system is the acoustic tomography transceiver and its associated acoustic navigation grid. To this basic system, a link to the surface has been added to provide a pathway for telemetry of the tomographic data to shore and a downlink for satellite-derived time which is used to correct the transceiver's clock. The surface buoy contains a GPS receiver, clock comparator, system controller, and multiple ID Argos transmitters. Processed tomography signals, transceiver location data, time, time drift, and surface buoy engineering data are transmitted to a satellite using a total of 32 data buffers transmitted every eight minutes. The report describes the real-time tomography system in detail, with particular emphasis on the modifications implemented to convert the standard tomography instrument to a real-time oceanographic tool. AN INVESTIGATION USING EMPIRICAL ORTHOGONAL FUNCTIONS AND OBJECTIVE ANALYSIS TO ANALYSE THE VERTICAL TEMPERATURE STRUCTURE OF A GULF STREAM MEANDER M.S. Thesis
Martin J. Sauze Mar. 1993 157 p
(AD-A265116) Avail: CASI HC A08/MF A02

Expendable bathymetric temperature (XBT) data taken from an anticyclonic meander crest within the Gulf Stream is analyzed by looking at the empirical vertical structure. The ensemble averaged data is formed into a projection matrix that compares the value of the temperature at one depth with the temperature at a second depth. The data was smoothed with the correlation analysis being performed at ten metre intervals from five metres to a depth of 800 metres. The first four empirical orthogonal functions (EOF's) of the projection matrix were computed and the modal amplitudes for each XBT determined. Using objective analysis the modal amplitudes were interpolated onto a specified grid. Synthetic XBT's were then reconstructed at the grid positions using the interpolated grid modal amplitude values. A measure of the error at each grid point was determined. The objective analysis was subsequently repeated using successively fewer XBT's from the data set, until the resulting error in the interpolated XBT's at the grid points became unacceptable. DTIC

SHEAR, STRAIN AND THERMOHALINE VERTICAL FINE STRUCTURE IN THE UPPER OCEAN Ph.D. Thesis
Steve P. Anderson Jan. 1993 154 p
(Contract N00014-90-J-1099)
(AD-A265961; MPL-U-4/93; SIO-REF-93-3) Avail: CASI HC A08/MF A02

Observations of fine scale (1-100m) vertical shear, strain and thermohaline structure are interpreted in terms of internal wave and frontal zone dynamics. The date were collected with the Marine Physical Laboratory 161 kHz Doppler sonar and a pair of CTD's. The two systems were operated from R/P FLIP for 18 days during February-March, 1990, as part of the SWAPP (35 deg N, 127 deg W) experiment. These simultaneous measurements of velocity and density provide a unique opportunity to study the vertical advection of shear layers. The observed shear variance is dominated by near inertial waves, with 35 m vertical wavelengths. These inertial waves propagate down from the mixed layer and are vertically advected by higher frequency waves. Vertical wavenumber-frequency spectra of shear and strain are examined in Eulerian (fixed depth) and semi-Lagrangian (isopyncal following) coordinates. The semi-Lagrangian shear and strain variances are more consistent with variances modeled by a linear superposition of internal waves. The pdf's of buoyancy frequency and Froude number (buoyancy normalized shear) are determined using the kinematic strain model of Pinkel and Anderson. The Froude number distribution shows good agreement with data presented here and historical data. The advection of a frontal zone past the experiment site yielded detailed observations of frontal interleaving. Two vertical interleaving scales are observed. DTIC

PRELIMINARY ANALYSIS OF THE FLIP ARRAY DATA FROM THE NOBS EXPERIMENT
M. T. Hagerty, G. L. DSpain, and W. S. Hodgkiss May 1992 85 p
(Contract N00014-89-D-0142)
(AD-A265911; MPL-TM-429; MPL-U-42/92) Avail: CASI HC A05/MF A01

Preliminary analysis of the data collected by the array suspended below R/P FLIP (FLoating Instrument Platform) during the Noise Over Basalts and Sediments (NOBS) experiment are presented. This report gives a description of the FLIP array, a summary of the tape log kept aboard FLIP, a summary of the quality of the data collected, and the results of some initial data analysis. The initial examination of the data shows that a total of 36 vertical line array (VLA) hydrophones and all four channels of four ocean bottom seismometers (OBS) provided useable data. The quality of the recorded data is variable, but remains rather high for extended periods of time, especially for the 10 hours of data on tape 7. Analysis of tape 7's data indicates that the calibrated ambient noise spectra estimated from the VLA hydrophones data agree well with predicted noise levels in moderate to heavy shipping regions. At times, these spectra contain a peak centered at 18 Hz, which is probably indicative of the presence of whales. In addition, ship-generated signals are clearly visible in the spectra at those times when surface ship sightings were noted in the experiment log. Finally, large amplitude signals of unknown origin were observed in the root mean squared (RMS) time series plots for all functioning data channels. The coherence function estimates between the OBS hydrophones and between the VLA hydrophones for the large arrivals are consistent with a horizontally propagating acoustic wave. DTIC

MAPPING BATHYMETRIC SLOPES FROM BATHYMETRY DATA Final Report
Christian DeMoustier May 1993 4 p
(Contract N00014-89-J-3174)
(AD-A265923; MPL-U-26/93) Avail: CASI HC A01/MF A01

The objectives of this work were to develop slope calculation and mapping algorithms for use with Sea Beam bathymetry data. The ability to quantify and map in geographic coordinates apparent bottom slopes, as measured by the sonar in a given region, provides important clues for the level of acoustic bottom reverberation that can be expected from the region on purely geometric grounds DTIC

MICROBIOLOGICAL TEST RESULTS USING THREE URINE PRETREATMENT REGIMES WITH 316L STAINLESS STEEL

Timothy L. Huff Jul. 1993 19 p Original contains color illustrations
(Contract NAS8-37814)
(NASA-CR-192568; NAS 1.26:192568) Avail: CASI HC A03/MF A01; 2 functional color pages

Three urine pretreatments, (1) Oxone (Dupont) and sulfuric acid, (2) sodium hypochlorite and sulfuric acid, (3) and ozone, were studied for their ability to reduce microbial levels in urine and minimize surface attachment to 316L stainless steel coupons. Urine samples inoculated with Bacillus insolitus and a filamentous mold, organisms previously recovered from the vapor compression distillation subsystem of NASA Space Station Freedom water recovery test were tested in glass corrosion cells containing base or weld metal coupons. Microbial levels, changes in pH, color, turbidity, and odor of the fluid were monitored over the course of the 21-day test. Specimen surfaces were examined by scanning electron microscopy at completion of the test for microbial attachment. Ozonated urine samples were less turbid and had lower microbial levels than controls or samples receiving other pretreatments. Base metal coupons receiving pretreatment were relatively free of attached bacteria. However, well-developed biofilms were found in the heat-affected regions of welded coupons receiving Oxone and hypochlorite pretreatments. Few bacteria were observed in the same regions of the ozone pretreatment sample. Author (revised)

CONVERSION OF ACETIC ACID TO METHANE BY THERMOPHILES
S. H. Zinder 1993 13 p
(Contract DE-FG02-85ER-13370)
(DE93-014433; DOE/ER-13370/T2) Avail: CASI HC A03/MF A01

The primary goal of this project is to obtain a better understanding of thermophilic microorganisms which convert acetic acid to CH4. The previous funding period represents a departure from earlier research in this laboratory which was more physiological and ecological. The present work is centered on the biochemistry of the thermophile Methanothrix sp. strain CALS-1. This organism presents a unique opportunity, with its purity and relatively rapid growth, to do comparative biochemical studies with the other major acetotrophic genus Methanosarcina. We previously found that Methanothrix is capable of using acetate at concentrations 100 fold lower than Methanosarcina. This finding suggests that there are significant differences in the pathways of methanogenesis from acetate in the two genera. DOE

(NASA-CR-193232; NAS 1.26:193232) Avail: CASI HC A03/MF A01

The consequences of headward fluid shifts during manned spaceflight was studied. Such shifts were recognized early by both U.S. and Soviet scientists because of signs and symptoms referable to the head. Some of these include disturbed vision, puffiness in the face and periorbital areas, headache, vestibular dysfunction, and distended jugular veins. We posited that the fluid shift had an immediate effect on the brain and a long-term action requiring a neural interpretation of the flight environment. This would re-adjust both efferent neural as well as hormonal mechanisms to sustain cardiovascular and fluid/electrolyte balance consonent with survival in microgravity. Work along these lines is summarized. A synopsis of some of the main research is presented. The following topics were studied: (1) angiotensin and vasopressin action in the central nervous system; (2) intracranial pressure control; (3) research on subcommissural organ; and (4) research on the eye. EFFECT OF DOUBLE DENSITY CAGING DURING SPACE SHUTTLE TRANSPORT OF LABORATORY RATS Final Report
G. L. Riskowski, H. W. Gonyou, P. C. Harrison, K. W. Kelley, and M. E. Tumbleson 22 Jun. 1993 100 p
(Grant NAG2-736)
(NASA-CR-193228; NAS 1.26:193228) Avail: CASI HC A05/MF A02; 1 functional color page

Male Sprague Dawley rats were housed in groups of four in polycarbonate cages at recommended density and thermal environmental conditions for 14 days prior to testing to ensure uniform acclimation to those conditions. Body weights averaged 286 +/- 7 g at the end of acclimation. Rat cages were assigned randomly to three treatments: (1) 4 rats/polycarbonate cage (877 sq cm, 20.3 cm high, 220 sq cm/rat), (2) 4 rats/mock AEM (MAEM) (620 sq cm, 155 sq cm/rat), and (3) 8 rats/MAEM (620 sq cm, 77.5 sq cm/rat). A comparison between the MAEM-DD and MAEM-SD treatments was done to determine if doubling rat density in AEM's stressed the rats. A comparison among MAEM treatments and the PC treatment was done to determine if any stress indications were due to the AEM. During this density challenge phase, all treatments were maintained at the same thermal environmental conditions (22.5 C and 50 percent RH) for 10 days. After the density challenge phase, half the rats from each group were sacrificed for body tissue and fluid analyses. The remaining half of the rats were housed at a density of 4 rats/cage in polycarbonate cages at normal thermal environmental conditions for an additional 10 days to determine if there were any differences in responses between treatments after a recovery period. The remaining rats were examined and sacrificed for body tissue and fluid analyses at the end of the recovery phase. Author (revised)

EXERCISE COUNTERMEASURES FOR BED-REST DECONDITIONING Final Report, 1986
John Greenleaf, ed. Jun. 1993 216 p
(RTOP 199-21-12-07)
(NASA-TM-103987; A-93008; NAS 1.15:103987) Avail: CASI HC A10/MF A03

The purpose for this 30-day bed rest study was to investigate the effects of short-term, high intensity isotonic and isokinetic exercise training on maintenance of working capacity (peak oxygen uptake), muscular strength and endurance, and on orthostatic tolerance, posture and gait. Other data were collected on muscle atrophy, bone mineralization and density, endocrine analyses concerning vasoactivity and fluid-electrolyte balance, muscle intermediary metabolism, and on performance and mood of the subjects. It was concluded that: The subjects maintained a relatively stable mood, high morale, and high esprit de corps throughout the study. Performance improved in nearly all tests in almost all the subjects. Isotonic training, as opposed to isokinetic exercise training, was associated more with decreasing levels of psychological tension, concentration, and motivation; and improvement in the quality of sleep. Working capacity (peak oxygen uptake) was maintained during bed rest with isotonic exercise training; it was not maintained with isokinetic or no exercise training. In general, there was no significant decrease in strength or endurance of arm or leg muscles during bed rest, in spite of some reduction in muscle size (atrophy) of some leg muscles. There was no effect of isotonic exercise training on orthostasis, since tilt-table tolerance was reduced similarly in all three groups following bed rest. Bed rest resulted in significant decreases of postural stability and self-selected step length, stride length, and walking velocity, which were not influenced by either exercise training regimen. Most pre-bed rest responses were restored by the fourth day of recovery. Author (revised)

SPACELAB J AIR FILTER DEBRIS ANALYSIS Interim Report
Donald C. Obenhuber Jul. 1993 11 p
(Contract NAS8-37814)
(NASA-CR-192569; NAS 1.26:192569; STS-49-SLJ) Avail: CASI HC A03/MF A01

Filter debris from the Spacelab module SLJ of STS-49 was analyzed for microbial contamination. Debris for cabin and avionics filters was collected by Kennedy Space Center personnel on 1 Oct. 1992, approximately 5 days postflight. The concentration of microorganisms found was similar to previous Spacelab missions averaging 7.4E+4 CFU/mL for avionics filter debris and 4.5E+6 CFU/mL for the cabin filter debris. A similar diversity of bacterial types was found in the two filters. Of the 13 different bacterial types identified from the cabin and avionics samples, 6 were common to both filters. The overall analysis of these samples as compared to those of previous missions shows no significant differences. Author

RESEARCH ON ACOUSTIC COUPLING TO ELECTROMAGNETIC PULSES IN TISSUE Final Report, 1 Apr. 1988 - 31 Mar. 1993
Harry Moses 15 Apr. 1993 4 p
(Contract F49620-88-C-0070)
(AD-A264764; AFOSR-93-0334TR) Avail: CASI HC A01/MF A01

Over the course of the contract, Dr. Moses published 12 papers, and one is still pending. His work on novel electromagnetic wave propagation, together with insights regarding possible transmitters, is nothing short of terminal. Dr. Moses was the first to rigorously characterize the universal character of far field patterns produced by a source that operated over a finite time frame. Such patterns could be 'requested' and then the design/operating procedure of the source would be the fundamental unknown. Such possibilities were communicated to government lab researchers at AL (Brooks AFB), and subsequent work will be pursued by Dr. Moses, with their help. DTIC

(AD-A264957) Avail: CASI HC A03

With few exceptions, membrane lipids are usually regarded as a kind of filler or passive solvent for membrane proteins. Yet, cells exquisitely control membrane composition. Many phospholipids found in plasma membrane bilayers favor packing into inverted hexagonal bulk phases. It was suggested that the strain of forcing such lipids into a bilayer may affect membrane protein function, such as the operation of trans-membrane channels. To investigate this, we have inserted the peptide alamethicin into bilayer membranes composed of lipids of empirically determined inverted hexagonal phase 'spontaneous radii' Ro, which will have expectably different degrees of strain when forced into bilayer form. We observe a correlation between measured Ro and the relative probabilities of different conductance states. States of higher conductance are more probable in Dioleoyl Phosphatidyl Ethanolamine (DOPE), the lipid of highest curvature, 1/Ro, than in Dioleoyl Phosphatidyl Choline (DOPC), the lipid of lowest curvature. MOMENTUM INDUCED BY LASER-TISSUE INTERACTION
R. S. Dingus 1993 14 p Presented at the OE/LASE 1993: International Society for Optical Engineering (SPIE) Conference, Los Angeles, CA, 16-23 Jan. 1993
(Contract W-7405-eng-36)
(DE93-010737; LA-UR-93-1099; CONF-930159-22) Avail: CASI HC A03/MF A01

Impulsive momentum is imparted to residual tissue during pulsed-laser ablation because the mass ablated is generally ejected with a sizable velocity. Accurate measurements of the impulse are possible, which can provide an important monitor of the ablation process. Simple models can be used to predict the impulse under a variety of conditions; in some cases, complex radiation-hydrodynamic code calculations are required. In this paper, this modeling is discussed along with the dependence of momentum on the pulsed heating and target conditions. Momentum measurement techniques are discussed briefly. The behavior is explained in terms of dimensionless parameters and the impulse coupling coefficient as a function of incident fluence, which has a well defined threshold as well as a maximum. Complications in the mixed liquid-vapor phase are also addressed. DOE

EFFECT OF INTERMITTENT COLD EXPOSURE ON THE FIBER-TYPE COMPOSITION OF SELECTED SKELETAL MUSCLES IN RATS Final Technical Report, Mar. - Nov. 1990
Thomas J. Walters and Stefan H. Constable Apr. 1993 20 p
(AD-A265309; AL-TR-1992-0099) Avail: CASI HC A03/MF A01

The effect of long-term intermittent cold exposure (CE) on the fiber-type composition of the predominantly type I soleus and the predominantly type IIb extensor digitorum longus (EDL) muscles of the rats was examined. CE was accomplished by submerging the rats in shoulder-deep water, maintained at 20 +/- 0.5 C, for 1 h/d, 5 d/wk, for up to 19 weeks. Rats were randomly assigned to either a Control (CON) or Cold Exposure group. The efficacy of the treatment was tested by subjecting both groups to 20 C water for 45 minutes while measuring rectal temperature (T(sub re)) and VO2. The CE group displayed a 22% smaller reduction in T(sub re) (p less than 0.05) at the end of the exposure, and had a 23% greater VO2 (p less than 0.05) during the same period. Fiber-type composition was determined using routine histochemical methods for myosin-ATPase. The soleus muscle of the CE rats underwent a 156% increase in the number of type IIa fibers (p less than 0.05), with a 24% reduction in type I fibers (p less than 0.05). CE had no significant influence on the fiber-type composition of the EDL muscle. CE resulted in an increase in citrate synthase activity of 20% and 22% in the soleus and EDL muscles, respectively (p less than 0.05). It was demonstrated that intermittent CE induces a type I-to-type IIa transformation in the soleus muscle while having no influence on the EDL muscle. DTIC

COMPATIBILITY TESTS FOR BIOLOGICAL SPECIMENS TO ON-BOARD EXPERIMENTS IN THE SPACE SHUTTLE FLIGHT [SHATORU TOUSAI JIKKENYOU SEIBUTSU SHIRYOU NO TOUSAISEI KAKUNIN SHIKEN]
Tokyo, Japan National Space Development Agency 31 Mar. 1993 22 p In ENGLISH and JAPANESE
(NASDA-CNT-930003; JTN-93-80457) Avail: CASI HC A03/MF A01

A summary of the results of the verification test in accordance with the compatibility verification test requirements for biological specimen to onboard experiment is presented. Studies of the following items were conducted to optimize the electrophoresis conditions, sample concentrations, sample storage conditions, and electrophoresis chamber cleansing methods and to verify that the samples can be carried onboard as electrophoresis experiment samples: (1) keeping microorganism cells; (2) electrophoresis parameter test; (3) optical detection sensitivity of electrophoresis test samples; (4) recovery rate of post-electrophoresis samples; (5) electrophoresis chamber cleansing conditions; and (6) sample stability after electrophoresis. The electrophoresis of Salmonella typhimurium strains, detection of the electrophoresis of Salmonella typhimurium cells, absorbances of the collected fractions, effects of electrophoresis on the visibility of Salmonella typhimurium, efficiency of the bio-cleaning, etc. are shown. THE ORGANIZATION OF THE SUPRACHIASMATIC CIRCADIAN PACEMAKER OF THE RAT AND ITS REGULATION BY NEUROTRANSMITTERS AND MODULATORS Annual Report, 1 Apr. 1990 - 31 Mar. 1993
Martha U. Gillette, Steven J. DeMarco, Jian M. Ding, Eve A. Gallman, and Lia E. Faiman 18 May 1993 18 p
(Grant AF-AFOSR-0205-90)
(AD-A266113; AFOSR-93-0423TR) Avail: CASI HC A03/MF A01

The long-term goal of these studies is to understand how cells of the suprachiasmatic nucleus (SCN) are organized to form a 24-h biological clock and what roles specific neurotransmitters and modulators play in timekeeping and resetting processes. We address these questions by assessing the pattern of spontaneous neuronal activity using extracellular and whole cell patch recording techniques in long-lived SCN brain slices from rats. We have observed that a robust pacemaker persists in the ventrolateral region of microdissected SCN and have begun to define the electrophysiological properties of neurons in this region. Further, we are investigating changing sensitivities of the SCN to resetting by exogenous neurotransmitters, such as glutamate, serotonin and neuropeptide Y, across the circadian cycle. Our findings emphasize the complexity of organization and control of mammalian circadian timing. DTIC

LOCUS COERULEUS, VIGILANCE, AND STRESS: BRAIN MECHANISMS OF ADAPTIVE BEHAVIORAL RESPONSIVENESS Final Technical Report, 15 Dec. 1989 - 31 Dec. 1992
Gary A. Jones 13 May 1993 48 p
(Grant AF-AFOSR-0147-90)
(AD-A265657; AFOSR-93-0399TR) Avail: CASI HC A03/MF A01

We have developed techniques for recording stable unit activity from individual monkey locus coeruleus (LC) neurons using microwire electrodes (25 micrometers diameter). A combination of improved electrode design, new microadvancer, and methods to accurately localize the LC nucleus now permits stable recordings of high signal/noise (better than 3/1) from single neurons in the LC for several hours in the waking monkey performing a vigilance task. We have found that LC neurons vary activity phasically and tonically during vigilance performance. Phasic responses are selectively evoked by target cues, and follow new targets during acquisition of reversal in this task. Tonically, LC neurons vary activity levels in accordance with attentiveness to the task, as measured by the frequency of foveating a fix spot required to initiate each trial. Results indicate that the LC functions to regulate the lability of attention. In this view, performance on a task requiring focused attention varies with tonic LC activity in an inverted U relationship. Too little LC activity is associated with poor performance due to non-alertness, while high tonic LC activity corresponds to highly labile attention that prevents focusing attention for long time epochs. Together, these results indicate that optimal vigilance performance (e.g., radar monitoring activity) may require an intermediate level of LC activity and high phasic responsiveness of LC neurons. PLANT ARCHITECTURE, GROWTH AND RADIATIVE TRANSFER FOR TERRESTRIAL AND SPACE ENVIRONMENTS Final Report, 1 Feb. 1989 - 31 Jan. 1993
John M. Norman and Narendra S. Goel (State Univ. of New York, Binghamton.) 1993 9 p
(Grant NAGw-1575)
(NASA-CR-193476; NAS 1.26:193476) Avail: CASI HC A02/MF A01

The overall objective of this research was to develop a hardware implemented model that would incorporate realistic and dynamic descriptions of canopy architecture in physiologically based models of plant growth and functioning, with an emphasis on radiative transfer while accommodating other environmental constraints. The general approach has five parts: a realistic mathematical treatment of canopy architecture, a methodology for combining this general canopy architectural description with a general radiative transfer model, the inclusion of physiological and environmental aspects of plant growth, inclusion of plant phenology, and integration. AVIATION ACCIDENT RISK FOR AIRMEN WITH APHAKIA AND ARTIFICIAL LENS IMPLANTS Final Report
Van B. Nakagawara and Kathryn J. Wood Jul. 1993 15 p
(DOT/FAA/AM-93/11) Avail: CASI HC A03/MF A01

Airmen with aphakia and intraocular (IOL) implants who, on a case-by-case basis, may obtain a waiver for a medical certificate, have been previously associated with higher aviation accident rates when compared to the total civil airman population. This study analyzes the accident frequencies of these civil airmen for a 4-year period (1982-85). Medical records were evaluated for all certified airmen who carried FAA-specific pathology codes for aphakia and artificial lens implants during the study period. Aviation accident and active airman population frequencies were obtained from FAA databases. The entire population of aphakia and IOL airmen and those less than 50 years of age had significantly higher (p less than .50) accident rates than the corresponding non-aphakic airman population. Aeromedical certification considerations of the study findings are discussed. Further investigations into additional confounding factors between the aphakic and non-aphakic populations are recommended. Author

THE 2ND ANNUAL MEETING OF THE SOCIETY FOR RESEARCH ON BIOLOGICAL RHYTHMS Final Report, 1 Mar. 1992 - 1 Mar. 1993
Fred W. Turek (Northwestern Univ., Evanston, IL.) 30 Apr. 1993 121 p
Meeting held in Jacksonville, FL, 9-13 May 1990
(Contract F49620-92-J-0181)
(AD-A264869; AFOSR-93-0345TR) Avail: CASI HC A06/MF A02

From 6-10 May 1992, the Society for Research on Biological Rhythms held its third meeting at Amelia Island Plantation, Florida. The Society was formed in 1987 to promote the advancement of basic and applied research in all aspects of biological rhythms, to disseminate important research results concerning biological rhythms to the general public, to develop and enhance the education and training of students and researchers in the field, and to foster interdisciplinary communication. This third meeting was successful in meeting the goals of the Society, particularly in the area of interdisciplinary communication. Researchers in the field of Biological Rhythms tend to be fragmented into many disciplines and are often divided along many different lines. One way of dividing the field is along frequency lines; while some workers study biological rhythms with a period of msec, others are interested in rhythms with periods in the range of minutes, hours (i.e. ultradian or pulsatile), a day (i.e. circadian), or a year (i.e. seasonal or circannual). The field is also divided along the lines of the major disciplines within biology since rhythms biologists can be either biochemists, molecular/cellular biologists, system physiologists, behaviorists, or ecologists. In addition, while many workers study the basic biological mechanisms involved in generating rhythmicity, others are interested in the clinical applications of a better understanding of biological rhythmicity. Even within the clinical field, researchers fall into many traditional categories including psychiatry, endocrinology, neurology, oncology, cardiology, and reproduction. DTIC

P2NBC2 HEAT STRAIN DECISION AID. USER'S GUIDE, VERSION 2.1
Apr. 1993 51 p
(Contract DAAL02-90-C-0071)
(AD-A266072) Avail: CASI HC A04/MF A01

This report describes the capabilities and proper use of the P2NBC2 Heat Strain Decision Aid Software System. The P2NBC2 HSDA is a stand alone analytical tool for evaluating the effects of heat stress on soldier performance limits. User inputs include clothing type/chemical protective posture, activity level based on military task type, soldier anthropometric characteristics and acclimatization status, and environmental conditions (air temperature, wind speed, humidity, and solar radiation). The P2NBC2 HSDA provides color graphics, tabular, and data file outputs for heat casualty risk, sustainable work/rest cycle limits, maximum safe work time, and associated drinking water requirements. LARGE ARRAY SQUID MAGNETOMETER FOR NDE Annual Report, 1 Apr. 1992 - 1993
Douglas N. Paulson 27 Apr. 1993 16 p
(Contract F49620-92-C-0026)
(AD-A264799; AFOSR-93-0348TR) Avail: CASI HC A03/MF A01

Tristan Technologies, Inc. is working to apply SQUID magnetometry to problems in nondestructive evaluation which are important to the Strategic Defense Initiative. We have designed and are nearing completion of an innovative Non Destructive Evaluation (NDE) instrument that, unlike most existing instruments, can be used for studying deep sources with applied fields. We will assess the effectiveness of this SQUID NDE system for a broad range of nondestructive evaluation problems related to high-performance aircraft bearings, nuclear reactor fuel tubes, titanium billets for aircraft turbine blades, high-temperature superconducting magnetic shields, and riveted joints in military and commercial aircraft. In various applications, SQUID magnetometers could facilitate the development of high-performance devices, reduce manufacturing costs, monitor performance and assure quality control in manufacturing, and help prevent catastrophic failures of aircraft, satellites, weapons and other military systems. During Phase 3 we will design and commercialize instruments specifically to meet the most promising NDE applications for SQUID magnetometers. DTIC

N94-11649 Tripler Army Medical Center, Honolulu, HI. Dept. of Clinical Investigation.
THE DEPARTMENT OF CLINICAL INVESTIGATION, REPORTS CONTROL SYMBOL MED-300(R-1) Annual Progress Report, Fiscal Year 1992
1 Oct. 1992 53 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A264969) Avail: CASI HC A04

The Tripler Department of Clinical Investigation had an exciting year in FY-92. Despite serious challenges to research in the form of personnel freezes, funding cuts, and increasing demands on health care professionals to provide clinical services, there was no significant fall in research productivity. More impressively, Dr. Cathy Yamauchi-Uyehara was awarded an American Heart Association grant after submitting the highest ranked proposal for the AHA district. This was made more significant in view of the AHA policy to not award grants to military investigators. The Joint Tripler AMC/Kapiolani Medical Center for Women and Children's Neonatal Fellowship Program, which conducts all non-human studies in Tripler's DCI, has continued to maintain its position at the forefront of neonatal pulmonary medicine. The contributions of Dr. John Claybaugh, Tripler's senior scientist, to both research and administration of DCI are undiminished. MAJ Thomas Mundie has provided inspiration to all phases of research at Tripler, and especially to the Joint Neonatal Fellowship Program. DTIC

VISUAL PSYCHOPHYSICS OF EGOMOTION Interim Report, 1 Feb. 1992 - 31 Jan. 1993
Kathleen Turano 2 Mar. 1993 7 p
(Grant AF-AFOSR-0154-91)
(AD-A265253; AFOSR-93-0259TR) Avail: CASI HC A02/MF A01

One study investigated, under two viewing conditions, an observer's ability to determine whether she/he was moving forward along a straight or curved path using simulations of optic flow patterns. In one condition, the retinal image was stabilized against the effects of eye movements, in the other condition, eye movements were unrestricted. Stabilizing the retinal image decreased performance at slow speeds. A second study further explored the role of eye movements in the perception of motion. Speed-difference thresholds were measured under conditions of stabilized and free-viewing conditions. Despite the fact that eye movements can alter the direction and speed of the retinal-image motion relative to the stimulus motion, observers were able to judge speed differences in the free-viewing condition as well as in the stabilized-viewing condition, with the exception of the slowest speed. At the slowest speed, observers were able to detect smaller speed differences in the free-viewing condition. A third study determined the optimal stimulus for motion detection by searching the spatiotemporal stimulus whose direction was identified with least contrast energy. The best stimulus was determined to be at 3 cycles/deg, 1.67 deg/s with bandwidths of 7.06 Hz and 1-0.5 octaves. DTIC

INTERNATIONAL TELEMEDICINE/DISASTER MEDICINE CONFERENCE: PAPERS AND PRESENTATIONS
1991 271 p Conference held in Bethesda, MD.; sponsored by Uniformed Services Univ. of the Health Sciences and AIAA
(NASA-NP-207; NAS 1.83:207) Avail: CASI HC A12/MF A03

The first International Telemedicine/Disaster Medicine Conference was held in Dec. 1991. The overall purpose was to convene an international, multidisciplinary gathering of experts to discuss the emerging field of telemedicine and assess its future directions; principally the application of space technology to disaster response and management, but also to clinical medicine, remote health care, public health, and other needs. This collection is intended to acquaint the reader with recent landmark efforts in telemedicine as applied to disaster management and remote health care, the technical requirements of telemedicine systems, the application of telemedicine and telehealth in the U.S. space program, and the social and humanitarian dimensions of this area of medicine. For individual titles, see N94-11788 through N94-11810.

Avail: CASI HC A02/MF A03

While the majority of Canadians live in a narrow strip about 200 miles wide just north of the 45th parallel, a significant proportion of the population lives in non-urban, remote and sometimes isolated areas. Given this widely dispersed population, the provision of health services has always been a challenge. A list of non-urban health needs include the following: consulting services; clinical laboratory resources; investigative techniques (e.g., EEG, radiology, ultrasound, nuclear medicine); continuing education for physicians, nurses and other health professionals; teaching and training programs for administrative and support staff (dietary, housekeeping, maintenance); community health education and improved general education for health workers and families. For nearly three decades physicians and other health care professionals in the United States and Canada have been exploring the application of telecommunications to health care in rural and remote areas. The terms telemedicine and telehealth are used interchangeably to describe this activity. The prefix 'tele' refers to distance and now includes all types of communication over distance that support health care and health educational programs. Actually, telemedicine is as old as the telephone, which is still the most widely used communications technology in health care. Author (revised)

Rayman (Aerospace Medical Association, Alexandria, VA.), and Ashot E. Sarkisian (Republic Diagnostic Center, Yerevan, Armenia.) et al *In its* International Telemedicine/Disaster Medicine Conference: Papers and Presentations 1991 22 p Submitted for publication (For primary document see N94-11787 01-52)
Avail: CASI HC A03/MF A03

The Telemedicine Spacebridge, a satellite mediated audio-video-fax link between four U.S. and two Armenian and Russian medical centers, permitted remote American consultants to assist Armenian and Russian physicians in the management of medical problems following the December 1988 earthquake in Armenia and the June 1989 gas explosion near Ufa. During 12 weeks of operations, 247 Armenian and Russian and 175 American medical professionals participated in 34 half-day clinical conferences. 209 patients were discussed, requiring expertise in 20 specialty areas. Telemedicine consultations resulted in altered diagnoses for 54, new diagnostic studies for 70, altered diagnostic processes for 47, and modified treatment plans for 47 of 185 Armenian patients presented. Simultaneous participation of several U.S. medical centers was judged beneficial; quality of data transmission was judged excellent. These results suggest that interactive consultation by remote specialists can provide valuable assistance to onsite physicians and favorably influence clinical decisions in the aftermath of major disasters. USE OF TELESCIENCE FOR BIOMEDICAL RESEARCH DURING SPACE FLIGHT
Carolyn L. Huntoon, Howard J. Schneider, and Gayle M. Karamanos (General Electric Co., Houston, TX.) *In* NASA, Washington, International Telemedicine/Disaster Medicine Conference: Papers and Presentations 1991 5 p (For primary document see N94-11787 01-52)
Avail: CASI HC A01/MF A03

When the U.S. first embarked on a manned space flight program, NASA's use of medical telescience was focused on crew health monitoring. In recent years, medical telescience use has been expanded to include support of basic research in space medicine. It enables ground support personnel to assist on-board crews in the performance of experiments and improves the quality and quantity of data return. NASA is continuing to develop its telescience capabilities. Future plans include telemedicine that will enable physicians on Earth to support crewmembers during flight and telescience that will enable investigators at their home institutions to support and conduct in-flight medical research. NASA's use of telescience for crew safety and biomedical research from Project Mercury to the present is described and NASA's plans for the future are presented. Author (revised)

GLOBAL CONSIDERATIONS FOR IMPLEMENTATION OF TELEMEDICINE
M. F. Lechat *In* NASA, Washington, International Telemedicine/Disaster Medicine Conference: Papers and Presentations 1991 6 p (For primary document see N94-11787 01-52)
Avail: CASI HC A02/MF A03

In Dec. 1989, the United Nations proclaimed the Decade 1990-1999 as the International Decade for Natural Disasters Reduction (IDNDR). The Decade identified a number of research programs. IDNDR, provides a unique opportunity to explore the potential offered by the emerging technologies, and to promote, develop, and support those technologies deemed adequate to make the next century a safer one, especially in the poorest countries of the world. But all this improvement cannot be accomplished in a vacuum. We must begin now to eliminate pitfalls and illusions. A new attitude must emerge. In the scope of reducing human damages resulting from disasters, we must reconsider the cross-cultural understanding, and reach a real awareness which combines humility with a sense of relativeness. Promoting the right context is essential to the mandate of the Decade. Derived from text

The potential for global outbreaks of tropical infectious diseases, and our ability to identify and respond to such outbreaks is a major concern. Rapid, efficient telecommunications is viewed as part of the solution to this set of problems - the means to link a network of epidemiological field stations via satellite with U.S. academic institutions and government agencies, for purposes of research, training in tropical medicine, and observation of and response to epidemic emergencies. At a workshop, telecommunications and technology transfer were addressed and applications of telecommunications technology in long-distance consultation, teaching and disaster relief were demonstrated. Applications in teaching and consultation in tropical infectious diseases is discussed. Derived from text

APPLICATIONS OF THE INTELSAT SYSTEM TO REMOTE HEALTH CARE

Andrea Maleter *In* NASA, Washington, International Telemedicine/Disaster Medicine Conference: Papers and Presentations 1991 9 p (For primary document see N94-11787 01-52)

Avail: CASI HC A02/MF A03

INTELSAT, the International Telecommunications Satellite Organization, is a not-for-profit commercial cooperate of 124 member nations, created on 20 August 1964. It owns and operates a global system of communications satellites that provides international telecommunications services to 180 countries, territories, and dependencies, and domestic telecommunications services to 40 nations. INTELSAT has actively encouraged the use of satellites for both telemedicine and disaster relief. Topics discussed include: INTELSAT domestic/regional services; use of transportable antennas; INTELNET; using the existing telecommunications infrastructure for remote health care applications: Project Access; INTELSAT's role in disaster telecommunications efforts; and how INTELSAT's existing infrastructure can be used for disaster telecommunications. CLINICAL ASPECTS OF TELEMEDICINE

Ronald C. Merrell *In* NASA, Washington, International Telemedicine/Disaster Medicine Conference: Papers and Presentations 1991 3 p (For primary document see N94-11787 01-52)

Avail: CASI HC A01/MF A03

Communication among physicians is an essential in order to combine our experiences for the elucidation and application of new knowledge and for the accurate and uniform application of established medical practice. This communication requires an adequate understanding of the culture of the patient and the social context of disease and indeed the culture of the physician. Malnutrition in Bangladesh means caloric insufficiency, and a program to lower cholesterol would be impertinent, while a program to enhance the nutrition of patients in Texas by an international effort to import more grain would be ludicrous. In the same vein a public health effort to combat alcoholic cirrhosis in Mecca would be as silly as a program to increase fiber in the diet of the Bantu. Clinical communication must acknowledge the culture of the issue at hand and the differences in the experiential base of the physicians. Not only do geography and culture affect the potential differences in the experiential bases, but the world utilizes very different traditions of education and science in training physicians. We are influenced by the diseases we treat, and learn to look for the expected at least as much as we are attentive to the unexpected. A physician in Siberia would be much more likely to recognize frostbite than one from Buenos Aires, and the Argentine doctor would much more likely consider Chaga's Disease to explain abdominal pain than a colleague in Zurich. Beyond these obvious issues in communication among physicians we must deal with the many languages and idioms used in the world. An overview of using Telemedicine SpaceBridge after the earthquake in the Republic of Armenia in 1988 is presented. Author (revised)

NEW TECHNOLOGY APPLIED TO TELEMEDICINE

Edward F. Miller *In* NASA, Washington, International Telemedicine/Disaster Medicine Conference: Papers and Presentations 1991 19 p (For primary document see N94-11787 01-52)

Avail: CASI HC A03/MF A03

Satellite communications technology was used for establishing international telemedicine communications links in a number of instances, (e.g., Telemedicine SpaceBridge between Armenia and the United States in 1989, and the proposed linkages shown, for demonstration during this conference and during 1992 and 1993). In the current example, geostationary satellites are used to provide intercontinental communications links between the two countries and also for distribution within each country. Author

LINKING MEDICAL RECORDS TO AN EXPERT SYSTEM

Frank Naeymi-Rad, David Trace, and Fabio DeSouzaAlmeida (Kaiser Medical Center, Santa Clara, CA.) *In* NASA, Washington, International Telemedicine/Disaster Medicine Conference: Papers and Presentations 1991 15 p (For primary document see N94-11787 01-52)

Avail: CASI HC A03/MF A03

This presentation will be done using the IMR-Entry (Intelligent Medical Record Entry) system. IMR-Entry is a software program developed as a front-end to our diagnostic consultant software MEDAS (Medical Emergency Decision Assistance System). MEDAS (the Medical Emergency Diagnostic Assistance System) is a diagnostic consultant system using a multimembership Bayesian design for its inference engine and relational database technology for its knowledge base maintenance. Research on MEDAS began at the University of Southern California and the Institute of Critical Care in the mid 1970's with support from NASA and NSF. The MEDAS project moved to Chicago in 1982; its current progress is due to collaboration between Illinois Institute of Technology, The Chicago Medical School, Lake Forest College and NASA at KSC. Since the purpose of an expert system is to derive a hypothesis, its communication vocabulary is limited to features used by its knowledge base. The development of a comprehensive problem based medical record entry system which could handshake with an expert system while creating an electronic medical record at the same time was studied. IMR-E is a computer based patient record that serves as a front end to the expert system MEDAS. IMR-E is a graphically oriented comprehensive medical record. The programs major components are demonstrated. Author (revised)

SPACE TECHNOLOGY IN REMOTE HEALTH CARE

Sam L. Pool *In* NASA, Washington, International Telemedicine/Disaster Medicine Conference: Papers and Presentations 1991 7 p (For primary document see N94-11787 01-52)

Avail: CASI HC A02/MF A03

Crews and passengers on future long-duration Earth orbital and interplanetary missions must be provided quality health services - to combat illnesses and accidental injuries, and for routine preventive care. People on Earth-orbital missions can be returned relatively easily to Earth, but those on interplanetary missions cannot. Accordingly, crews on long-duration missions will likely include at least one specially trained person, perhaps a physician's assistant, hospital corpsman, nurse, or physician who will be responsible for providing onboard health services. Specifically, we must determine the most effective way to administer health care to a remotely located population. NASA with the cooperation of the Department of Health, Education, and Welfare is pursuing a program for providing health services to remote locations on Earth as a necessary step to developing and verifying this capability on a spacecraft. The STARPAHC program is described. Author (revised)

NYNEX Science and Technology is engineering a multi-layered approach to multimedia communications by combining high-resolution images, video, voice, and text into a new fiber-optic service. The service, Media Broadband Service (MBS), is a network-based visual communications capability. It permits real time sharing of images in support of collaborative work among geographically dispersed locations. The health care industry was identified as a primary target market due to their need for high resolution images, the need to transport these images over great distances, and the need to achieve the transport in a short amount of time. The NYNEX Corporation, the current state of the MBS project, including the market needs driving the development of MBS, the overall design of the service, its current implementation and development status, and the progress of MBS projects underway for various customers participating in the initial service offering are described. Improved communications and space-science technologies, such as remote sensing, offer hope of new, more holistic approaches to combating many arthropod-borne disease problems. The promise offered by these technologies has surfaced at a time when global and national efforts at disease control are in decline. Indeed, these programs seem to be losing ground against the arthropod-borne diseases just as rapidly as we seem to be moving forward in technological development. Given these circumstances, we can only hope that remote sensing and geographic information system (GIS) technologies can be pressed into service to help target the temporal and spatial application of control measures and to help in developing new control strategies. A TELEMEDICINE HEALTH CARE DELIVERY SYSTEM
Jay H. Sanders *In* NASA, Washington, International Telemedicine/Disaster Medicine Conference: Papers and Presentations 1991 4 p (For primary document see N94-11787 01-52)
Avail: CASI HC A01/MF A03

The Interactive Telemedicine Systems (ITS) system was specifically developed to address the ever widening gap between our medical care expertise and our medical care delivery system. The frustrating reality is that as our knowledge of how to diagnose and treat medical conditions has continued to advance, the system to deliver that care has remained in an embryonic stage. This has resulted in millions of people being denied their most basic health care needs. Telemedicine utilizes an interactive video system integrated with biomedical telemetry that allows a physician at a base station specialty medical complex or teaching hospital to examine and treat a patient at multiple satellite locations, such as rural hospitals, ambulatory health centers, correctional institutions, facilities caring for the elderly, community hospital emergency departments, or international health facilities. Based on the interactive nature of the system design, the consulting physician at the base station can do a complete history and physical examination, as if the patient at the satellite site was sitting in the physician's office. This system is described. Author (revised)

COMMUNICATIONS INFRASTRUCTURE REQUIREMENTS FOR TELEMEDICINE/TELEHEALTH IN THE CONTEXT OF PLANNING FOR AND RESPONDING TO NATURAL DISASTERS: CONSIDERING THE NEED FOR SHARED REGIONAL NETWORKS
John Carver Scott *In* NASA, Washington, International Telemedicine/Disaster Medicine Conference: Papers and Presentations 1991 6 p (For primary document see N94-11787 01-52)
Avail: CASI HC A02/MF A03

During the course of recent years the frequency and magnitude of major disasters - of natural, technological, or ecological origin - have made the world community dramatically aware of the immense losses of human life and economic resources that are caused regularly by such calamities. Particularly hard hit are developing countries, for whom the magnitude of disasters frequently outstrips the ability of the society to cope with them. In many cases this situation can be prevented, and the recent trend in disaster management has been to emphasize the importance of preparedness and mitigation as a means of prevention. In cases of disaster, a system is needed to respond to relief requirements, particularly the delivery of medical care. There is no generic telecommunications infrastructure appropriate for the variety of applications in medical care and disaster management. The need to integrate telemedicine/telehealth into shared regional disaster management telecommunications networks is discussed. Focus is on the development of infrastructure designed to serve the needs of disaster prone regions of the developing world. Derived from text

INTERNATIONAL DISASTER RESEARCH
Martin Elliot Silverstein *In* NASA, Washington, International Telemedicine/Disaster Medicine Conference: Papers and Presentations 1991 4 p (For primary document see N94-11787 01-52)
Avail: CASI HC A01/MF A03

No existing telecommunications system can be expected to provide strategy and tactics appropriate to the complex, many faceted problem of disaster. Despite the exciting capabilities of space, communications, remote sensing, and the miracles of modern medicine, complete turnkey transfers to the disaster problem do not make the fit, and cannot be expected to do so. In 1980, a Presidential team assigned the mission of exploring disaster response within the U.S. Federal Government encountered an unanticipated obstacle: disaster was essentially undefined. In the absence of a scientifically based paradigm of disaster, there can be no measure of cost effectiveness, optimum design of manpower structure, or precise application of any technology. These problems spawned a 10-year, multidisciplinary study designed to define the origins, anatomy, and necessary management techniques for catastrophes. The design of the study necessarily reflects interests and expertise in disaster medicine, emergency medicine, telecommunications, computer communications, and forencsic sciences. This study is described. Derived from text

MEDICAL CARE DELIVERY IN THE US SPACE PROGRAM
Donald F. Stewart *In its* International Telemedicine/Disaster Medicine Conference: Papers and Presentations 1991 3 p (For primary document see N94-11787 01-52)
Avail: CASI HC A01/MF A03

The stated goal of this meeting is to examine the use of telemedicine in disaster management, public health, and remote health care. NASA has a vested interest in providing health care to crews in remote environments. NASA has unique requirements for telemedicine support, in that our flight crews conduct their job in the most remote of all work environments. Compounding the degree of remoteness are other environmental concerns, including confinement, lack of atmosphere, spaceflight physiological deconditioning, and radiation exposure, to name a few. In-flight medical care is a key component in the overall support for missions, which also includes extensive medical screening during selection, preventive medical programs for astronauts, and in-flight medical monitoring and consultation. This latter element constitutes the telemedicine aspect of crew health care. The level of in-flight resources dedicated to medical care is determined by the perceived risk of a given mission, which in turn is related to mission duration, planned crew activities, and length of time required for return to definitive medical care facilities. USE OF SATELLITE TELECOMMUNICATIONS FOR TELEMEDICINE

Gennady Tamkovich *In* NASA, Washington, International Telemedicine/Disaster Medicine Conference: Papers and Presentations 1991 5 p (For primary document see N94-11787 01-52)

Avail: CASI HC A01/MF A03

The use of space telecommunications facilities in the interests of medicine should establish a reliable and timely connection between the specialists involved and access for each of them to information sources the need. Since a certain global-scale program should be implemented for this goal to be achieved, one of the top-priority tasks is to determine appropriate orbital facilities for telecommunications as well as appropriate areas and countries for them, outlining the territories where portable data receive/transport records can be placed and stations that are cheap and simple enough to operate can be stored. Eventually the satellite telecommunications system should encourage health workers to unite in a world community on the basis of a regular and efficient information exchange with the goal of protecting the health of man and the peace of Earth. This goal could only be achieved by gradually removing differences in the domain of medical education and information in different regions over the globe, by providing a possibility of rapid and coordinated access to the information on medical problems of interest on the global scale, as well as by coordinating the discussion and solution of all problems associated with the development and progress of the satellite communications system.

USE OF LOW ORBITAL SATELLITE COMMUNICATIONS SYSTEMS FOR HUMANITARIAN PROGRAMS

Vladimir N. Vlasov and Vladimir Gorkovoy *In* NASA, Washington, International Telemedicine/Disaster Medicine Conference: Papers and Presentations 1991 9 p (For primary document see N94-11787 01-52)

Avail: CASI HC A02/MF A03

Communication and information exchange play a decisive role in progress and social development. However, in many parts of the world the communication infrastructure is inadequate and the capacity for on-line exchange of information may not exist. This is true of underdeveloped countries, remote and relatively inaccessible regions, sites of natural disasters, and of all cases where the resources needed to create complex communication systems are limited. The creation of an inexpensive space communications system to service such areas is therefore a high priority task. In addition to a relatively low-cost space segment, an inexpensive space communications systems requires a large number of ground terminals, which must be relatively inexpensive, energy efficient (using power generated by storage batteries, or solar arrays, etc.), small in size, and must not require highly expert maintenance. The ground terminals must be portable, and readily deployable. Communications satellites in geostationary orbit at altitudes of about 36,000 km are very expensive and require complex and expensive ground stations and launch vehicles. Given current technology, it is categorically impossible to develop inexpensive satellite systems with portable ground terminals using such satellites. To solve the problem of developing an inexpensive satellite communications system that can operate with relatively small ground stations, including portable terminals, we propose to use a system with satellites in low Earth orbit, at an altitude of 900-1500 km. Because low orbital satellites are much closer to the Earth than geostationary ones and require vastly less energy expenditure by the satellite and ground terminals for transmission of messages, a system using them is relatively inexpensive. Such a system could use portable ground terminals no more complex than ordinary mobile police radios. Author (revised)

THE REVITALIZATION OF HEALTH AND EDUCATION IN RURAL AMERICA ACT OF 1992

Glenn English *In* NASA, Washington, International Telemedicine/Disaster Medicine Conference: Papers and Presentations 1991 17 p (For primary document see N94-11787 01-52)

Avail: CASI HC A03/MF A03

During the preceding decade of the 1980's, rural communities witnessed an exodus of over 5 million residents to urban and suburban areas of the nation. It has become increasingly clear that rural parts of the country must adopt aggressive strategies to strengthen rural communities and enhance the quality of life for its citizens into the 21st century. Studies by the U.S. Department of Commerce, Office of Technology Assessment, and the Aspen Institute all identify advanced telecommunications systems as the linchpin for a vigorous future for rural America. The Revitalization of Health and Education in Rural America Act of 1992 incorporates these recommendations into viable strategies to improve health care and educational services for rural citizens. By linking up hospitals and schools through advanced telecommunications technology, vast geographic distances are instantly reduced. With the proper infrastructure in place, up-to-date telecommunications services will facilitate endless opportunities for improving the quality of life in remote areas. This comprehensive legislation is the critical first step in forging a partnership with urban communities to create an economically sound and technologically advanced America for generations to come. Improvement of health care and educational services in rural areas through the implementation of interactive telecommunications systems is addressed. A copy of the Act is included. Author (revised)

CAROTID-CARDIAC BAROREFLEX: RELATION WITH ORTHOSTATIC HYPOTENSION FOLLOWING SIMULATED MICROGRAVITY AND IMPLICATIONS FOR DEVELOPMENT OF COUNTERMEASURES

Abstract Only

Victor A. Convertino *In* Krug Life Sciences, Inc., Proceedings of the First Joint NASA Cardiopulmonary Workshop Apr. 1991 p 3-5 (For

primary document see N94-11991 01-52)
Avail: CASI HC A01/MF A02

In a series of studies, we have examined the effects of exposure to simulated microgravity, varying states of vascular volume, and acute exercise on the function of the carotid-cardiac baroreflex in man. In the first study, exposure to simulated microgravity (6 degree headdown bedrest) reduced the sensitivity and buffer capacity of the vagal baroreceptor-cardiac reflex mechanisms and this impaired baroreflex function was associated with orthostatic hypotension. Since the reduction in plasma volume during BR was not correlated with impaired baroreflex function, a second study was conducted which demonstrated that the carotid-cardiac baroreflex response was not affected by either acute hypovolemia or hypervolemia. These results suggest that acute fluid replacement prior to reentry may not reverse impaired baroreflex function associated with postflight hypotension. In a third study, we demonstrated that one bout of maximal exercise increased baroreflex sensitivity and buffer capacity through 24 h post-exercise. These baroreflex changes were opposite to those observed following BR. Taken together, these data suggest that the contributions of reduced blood volume and impaired carotid-cardiac baroreflex function to orthostatic hypotension following exposure to microgravity are probably separate and additive; maximal exercise in addition to fluid replacement may provide an acute effective countermeasure against postflight hypotension. ECHOCARDIOGRAPHY IN THE FLIGHT PROGRAM
John B. Charles, Michael W. Bungo, and Sharon L. Mulvagh *In* Krug Life Sciences, Inc., Proceedings of the First Joint NASA Cardiopulmonary Workshop Apr. 1991 p 7-9 (For primary document see N94-11991 01-52)
Avail: CASI HC A01/MF A02

Observations on American and Soviet astronauts have documented the association of changes in cardiovascular function during orthostasis with space flight. A basic understanding of the cardiovascular changes occurring in astronauts requires the determination of cardiac output and total peripheral vascular resistance as a minimum. In 1982, we selected ultrasound echocardiography as our means of acquiring this information. Ultrasound offers a quick, non-invasive and accurate means of determining stroke volume which, when combined with the blood pressure and heart rate measurements of the stand test, allows calculation of changes in peripheral vascular resistance, the body's major response to orthostatic stress. The history of echocardiography in the Space Shuttle Program is discussed and the results are briefly presented. Derived from text

PULMONARY FUNCTION IN MICROGRAVITY: KC-135 EXPERIENCE
Abstract Only
Harold J. Guy and G. K. Prisk *In* Krug Life Sciences, Inc., Proceedings of the First Joint NASA Cardiopulmonary Workshop Apr. 1991 p 11 (For primary document see N94-11991 01-52)
Avail: CASI HC A01/MF A02

We have commenced a KC-135 program that parallels and proceeds our Spacelab (SLS-1) pulmonary function experiment. Our first task was to elucidate the affect of normal gravitation on the shape of the maximum expiratory flow volume (MEFV) curve. Nine normal subjects performed multiple MEFV maneuvers at 0-G, 1-G, and approximately 1.7-G. The MEFV curves for each subject were filtered, aligned at RV, and ensemble-averaged to produce an average MEFV curve for each state, allowing differences to be studied. Most subjects showed a decrease in the FVC at 0-G, which we attribute to an increased intrathoracic blood volume. In most of these subjects, the mean lung volume associated with a given flow was lower at 0-G, over about the upper half of the vital capacity. This is similar to the change previously reported during heat out immersion and is consistent with the known affect of engorgement of the lung with blood, on elastic recoil. There were also consistent but highly individual changes in the position and magnitude of detailed features of the curve, the individual patterns being similar to those previously reported on transition from the erect to the supine position. This supports the idea that the location and motion of choke points which determine the detailed individual configuration of MEFV curves, can be significantly influenced by gravitational forces, presumably via the effects of change in longitudinal tension on local airway pressure-diameter behavior and wave speed. We have developed a flight mass spectrometer and have commenced a study of single breath gradients in gas exchange, inert gas washouts, and rebreathing cardiac outputs and lung volumes at 0-G, 1-G, and 1.7-G. Comparison of our results with those from SLS-1 should identify the opportunities and limitations of the KC-135 as an accessible microgravity resource. Author (revised)

GLYCEROL-INDUCED HYPERHYDRATION
Marvin L. Riedesel, Timothy P. Lyons, and M. Colleen McNamara *In* Krug Life Sciences, Inc., Proceedings of the First Joint NASA Cardiopulmonary Workshop Apr. 1991 p 37-49 (For primary document see N94-11991 01-52)
Avail: CASI HC A03/MF A02

Maintenance of euhydration is essential for maximum work performance. Environments which induce hypohydration reduce plasma volume and cardiovascular performance progressively declines as does work capacity. Hyperhydration prior to exposure to dehydrating environments appears to be a potential countermeasure to the debilitating effects of hypohydration. The extravascular fluid space, being the largest fluid compartment in the body, is the most logical space by which significant hyperhydration can be accomplished. Volume and osmotic receptors in the vascular space result in physiological responses which counteract hyperhydration. Our hypothesis is that glycerol-induced hyperhydration (GIH) can accomplish extravascular fluid expansion because of the high solubility of glycerol in lipid and aqueous media. A hypertonic solution of glycerol is rapidly absorbed from the gastrointestinal tract, results in mild increases in plasma osmolality and is distributed to 65 percent of the body mass. A large volume of water ingested within minutes after glycerol intake results in increased total body water because of the osmotic action and distribution of glycerol. The resulting expanded extravascular fluid space can act as a reservoir to maintain plasma volume during exposure to dehydrating environments. The fluid shifts associated with exposure to microgravity result in increased urine production and is another example of an environment which induces hypohydration. Our goal is to demonstrate that GIH will facilitate maintenance of euhydration and cardiovascular performance during space flight and upon return to a 1 g environment. Derived from text

SPECTRAL ANALYSIS OF RESTING CARDIOVASCULAR VARIABLES AND RESPONSES TO OSCILLATORY LBNP BEFORE AND AFTER 6 DEGREE HEAD DOWM BEDREST
Charles F. Knapp, J. M. Evans, A. Patwardhan, D. Levenhagen, M. Wang, and John B. Charles *In* Krug Life Sciences, Inc., Proceedings of the First Joint NASA Cardiopulmonary Workshop Apr. 1991 p 51-60 (For primary document see N94-11991 01-52)
Avail: CASI HC A02/MF A02

A major focus of our research program is to develop noninvasive procedures for determining changes in cardiovascular function associated with the null gravity environment. We define changes in cardiovascular function to be (1) the result of the regulatory system operating at values different from 'normal' but with an overall control system basically unchanged by the null gravity exposure, or (2) the result of operating with a control system that has significantly different regulatory characteristics after an exposure. To this end, we have used a model of weightlessness that consisted of exposing humans to 2 hrs. in the launch position, followed by 20 hrs. of 6 deg head down bedrest. Our principal objective was to use

this model to measure cardiovascular responses to the 6 deg head down bedrest protocol and to develop the most sensitive 'systems identification' procedure for indicating change. A second objective, related to future experiments, is to use the procedure in combination with experiments designed to determine the degree to which a regulatory pathway has been altered and to determine the mechanisms responsible for the changes.

EFFECT OF PROLONGED LBNP AND SALINE INGESTION ON PLASMA VOLUME AND ORTHOSTATIC RESPONSES DURING BED REST
Suzanne M. Fortney, Larry Dussack, Tracy Rehbein, Margie Wood, and Laura Steinmann *In* Krug Life Sciences, Inc., Proceedings of the First Joint NASA Cardiopulmonary Workshop Apr. 1991 p 61-70 (For primary document see N94-11991 01-52)

Avail: CASI HC A02/MF A02

Orthostatic intolerance remains a significant problem following space flight despite frequent use of the saline fluid-loading countermeasure and volitional use of an anti-gravity suite during reentry and landing. The purpose of this project is to examine the plasma volume (PV), endocrine, and orthostatic responses of bedrested subjects following 2-hr and 4-hr treatments of lower body negative pressure (LBNP) and saline ingestion. Ten healthy men were randomly assigned into 2 groups. Group A underwent a 4-hr LBNP/saline treatment on best rest day 5 and the 2-hr treatment on day 11. Group B underwent the 2-hr treatment on day 6 and the 4-hr treatment on day 10. Blood volume was determined before and after bed rest using radiolabelling. Changes in PV between measurements were calculated from changes in hematocrit and estimated red cell volume. Urinary excretion of anti-diuretic hormone (ADH) and aldosterone (ALD) were measured each day during the study. Orthostatic responses were measured using a ramp LBNP protocol before bed rest, before each treatment, and 24 hours after each treatment. Both 2-hr and 4-hr treatments resulted in a restoration of PV to pre-bed rest levels which persisted at least 24 hours. This increase in PV was associated with significant increases in urinary excretion of ADH and ALD. Twenty-four hours after the 4-hr treatment, the heart rate and pulse pressure response to LBNP were significantly lower and stroke volumes during LBNP were increased. Twenty-four hours after the 2-hr treatment, there was no evidence of improvement in orthostatic responses. These results suggest that a countermeasure which simply restores PV during space flight may not be sufficient for restoring orthostatic responses. Author

Work on this grant has consisted of two major studies of cardiovascular regulation in athletes along with several smaller supporting studies. This summary will give a brief overview of two major studies, and then conclude with an analysis of what the findings from these studies mean practically, and how they can be applied to current problems with post-flight orthostatic intolerance. The first study addresses a cross-sectional analysis of orthostatic intolerance in highly aerobically trained individuals; the second addresses ventricular pressure/volume relationships in athletes. VALSALVA MANEUVER: INSIGHTS INTO BAROREFLEX MODULATION OF HUMAN SYMPATHETIC ACTIVITY
Michael L. Smith, Dwain L. Eckberg, Janice M. Fritsch, Larry A. Beightol, and Kenneth A. Ellenbogen *In* Krug Life Sciences, Inc., Proceedings of the First Joint NASA Cardiopulmonary Workshop Apr. 1991 p 79-87 (For primary document see N94-11991 01-52)
Avail: CASI HC A02/MF A02

Valsalva's maneuver, voluntary forced expiration against a closed glottis, is a well-characterized research tool, used to assess the integrity of human autonomic cardiovascular control. Valsalva straining provokes a stereotyped succession of alternating positive and negative arterial pressure and heart rate changes mediated in part by arterial baroreceptors. Arterial pressure changes result primarily from fluctuating levels of venous return to the heart and changes of sympathetic nerve activity. Muscle sympathetic activity was measured directly in nine volunteers to explore quantitatively the relation between arterial pressure and human sympathetic outflow during pressure transients provoked by controlled graded Valsalva maneuvers. Our results underscore several properties of sympathetic regulation during Valsalva straining. First, muscle sympathetic nerve activity changes as a mirror image of changes in arterial pressure. Second, the magnitude of sympathetic augmentation during Valsalva straining predicts phase 4 arterial pressure elevations. Third, post-Valsalva sympathetic inhibition persists beyond the return of arterial and right atrial pressures to baseline levels which reflects an alteration of the normal relation between arterial pressure and muscle sympathetic activity. Therefore, Valsalva straining may have some utility for investigating changes of reflex control of sympathetic activity after space flight; however, measurement of beat-to-beat arterial pressure is essential for this use. The utility of this technique in microgravity can not be determined from these data. Further investigations are necessary to determine whether these relations are affected by the expansion of intrathoracic blood volume associated with microgravity. Author (revised)

MECHANISTIC STUDIES ON REDUCED EXERCISE PERFORMANCE AND CARDIAC DECONDITIONING WITH SIMULATED ZERO GRAVITY
Charles M. Tipton *In* Krug Life Sciences, Inc., Proceedings of the First Joint NASA Cardiopulmonary Workshop Apr. 1991 p 89-95 (For primary document see N94-11991 01-52)
(Grant NAG2-392)
Avail: CASI HC A02/MF A02

The primary purpose of this research is to study the physiological mechanisms associated with the exercise performance of rats subjected to conditions of simulated weightlessness. A secondary purpose is to study related physiological changes associated with other systems. To facilitate these goals, a rodent suspension model was developed (Overton-Tipton) and a VO2 max testing procedure was perfected. Three methodological developments occurred during this past year deserving of mention. The first was the refinement of the tail suspension model so that (1) the heat dissipation functions of the caudal artery can be better utilized, and (2) the blood flow distribution to the tail would have less external constriction. The second was the development on a one-leg weight bearing model for use in simulated weightlessness studies concerned with change in muscle mass, muscle enzyme activity, and hind limb blood flow. The chemical body composition of 30 rats was determined and used to develop a prediction equation for percent fat using underwater weighing procedures to measure carcass specific gravity and to calculate body density, body fat, and fat free mass. FLUID COMPARTMENT AND RENAL FUNCTION ALTERATIONS IN THE RAT DURING 7 AND 14 DAY HEAD DOWN TILT
Bryan J. Tucker *In* Krug Life Sciences, Inc., Proceedings of the First Joint NASA Cardiopulmonary Workshop Apr. 1991 p 97-108 Sponsored by NASA. Ames Research Center (For primary document see N94-11991 01-52)
(Grant NAG2-659)
Avail: CASI HC A03/MF A02

Exposure to conditions of microgravity for any extended duration can modify the distribution of fluid within the vascular and interstitial spaces, and eventually intracellular volume. Whether the redistribution of fluid and resetting of volume homeostasis mechanisms is appropriate for the long term environmental requirements of the body in microgravity remains to be fully defined. The event that initiates the change in fluid volume homeostasis is the cephalad movement of fluid which potentially triggers volume sensors and stretch receptors (atrial stretch with the resulting release of atrial natriuretic peptide) and suppresses adrenergic activity via the carotid and aortic arch baroreceptors. All these events act in concert to reset blood and interstitial volume to new levels, which in turn modify the renin-angiotensin system. All these factors have an influence on the kidney, the end organ for fluid volume control. How the fluid compartment volume changes interrelate with alterations in renal functions under conditions of simulated microgravity is the focus of the present investigation which utilizes 25-30 deg head-down tilt in the rat. Avail: CASI HC A03/MF A02

Local fluid shifts and edema in humans during simulated microgravity is studied. Recent results and significance and future plans on the following research topics are discussed: mechanisms of headward edema formation during head-down tilt; postural responses of head and foot microcirculations and their sensitivity to bed rest; and transcapillary fluid transport associated with lower body negative pressure (LBNP) with and without saline ingestion. HORMONAL REGULATION OF FLUID AND ELECTROLYTE METABOLISM IN ZERO-G AND BEDREST
Joan Vernikos *In* Krug Life Sciences, Inc., Proceedings of the First Joint NASA Cardiopulmonary Workshop Apr. 1991 p 121-139 (For primary document see N94-11991 01-52)
(RTOP 199-14-12-03)
Avail: CASI HC A03/MF A02

The study of man in spaceflight has consistently indicated changes in fluid and electrolyte balance. Sodium (Na), Potassium (K), and Calcium (Ca) excretion are increased, accompanied by changes in the levels and responsiveness of adrenal hormones and the sympathetic nervous system (SNS). These hormones and neurohumors are critical to the regulation of blood pressure, blood flow, and blood volume. The primary objectives of the research conducted under this task have been to use -6 deg head down bedrest (BR) as the analog to spaceflight, to determine the long term changes in these systems, their relationship to orthostatic tolerance, and to develop and test suitable countermeasures. HORMONAL REGULATION OF FLUID AND ELECTROLYTE METABOLISM DURING PERIODS OF HEADWARD FLUID SHIFTS
Lanny C. Keil, W. B. Severs (Pennsylvania State Univ., University Park.), T. Thrasher (California Univ., San Francisco.), and D. J. Ramsay (California Univ., San Francisco.) *In* Krug Life Sciences, Inc., Proceedings of the First Joint NASA Cardiopulmonary Workshop Apr. 1991 p 141-144 (For primary document see N94-11991 01-52)
Avail: CASI HC A01/MF A02

In the broadest sense, this project evaluates how spaceflight induced shifts of blood and interstitial fluids into the thorax affect regulation by the central nervous system (CNS) of fluid-electrolyte hormone secretion. Specifically, it focuses on the role of hormones related to salt/water balance and their potential function in the control of intracranial pressure and cerebrospinal fluid (CSF) composition. Fluid-electrolyte status during spaceflight gradually equilibrates, with a reduction in all body fluid compartments. Related to this is the cardiovascular deconditioning of spaceflight which is manifested upon return to earth as orthostatic intolerance. Author (revised)

AUTOGENIC-FEEDBACK TRAINING: A COUNTERMEASURE FOR ORTHOSTATIC INTOLERANCE
Patricia S. Cowings, William B. Toscano (California Univ., San Francisco.), Joe Kamiya (California Univ., San Francisco.), Neal E. Miller (Yale Univ., New Haven, CT.), and Thomas G. Pickering (Cornell Univ., New York, NY.) *In* Krug Life Sciences, Inc., Proceedings of the First Joint NASA Cardiopulmonary Workshop Apr. 1991 p 145-153 (For primary document see N94-11991 01-52)
Avail: CASI HC A02/MF A02

NASA has identified cardiovascular deconditioning as a serious biomedical problem associated with long-duration exposure to microgravity in space. High priority has been given to the development of countermeasures for this disorder and the resulting orthostatic intolerance experienced by crewmembers upon their return to the 1g norm of Earth. The present study was designed to examine the feasibility of training human subjects to control their own cardiovascular responses to gravitational stimulation (i.e., a tilt table). Using an operant conditioning procedure, Autogenic-Feedback Training (AFT), we would determine if subjects could learn to increase their own blood pressure voluntarily. Author (revised)

CARDIOVASCULAR DYNAMICS DURING SPACE SICKNESS AND DECONDITIONING
Ary L. Goldberger and David R. Rigney *In* Krug Life Sciences, Inc., Proceedings of the First Joint NASA Cardiopulmonary Workshop Apr. 1991 p 155-163 Sponsored by NASA. Ames Research Center (For primary document see N94-11991 01-52)
(Grant NAG2-514)
Avail: CASI HC A02/MF A01

We are currently funded by NASA for the project, 'Cardiovascular Dynamics During Space Sickness and Deconditioning.' NASA has given priority to the investigation of two problems encountered in the long-term space flights currently being planned: (1) space motion sickness; and (2) cardiovascular deconditioning. We have proposed to use spectral and nonlinear dynamical analysis of heart rate data to quantify the presence of these problems and to evaluate countermeasures against them. Author (revised)

PILOT TRIAL OF POTENTIATING NORMAL HEALING OF STRESS FRACTURES USING PULSING ELECTROMAGNETIC FIELDS Final Report, 15 Jan. 1991 - 14 Jan. 1993
Kent M. Karstetter, Richard A. Sherman, Howard May, and Paul Spezia 22 Feb. 1993 11 p Prepared for Army Medical Research and Development Command, Fort Detrick, MD
(Contract MIPR-91MM1519; DA Proj. 3M1-62787-A-874)
(AD-A264251) Avail: CASI HC A03/MF A01

Stress fractures usually take a long time to heal, and they prevent soldiers from participating in most physical activities. About half of the trainees at Ft. Sill diagnosed with stress fractures never return to active duty. This pilot program tests the feasibility of using pulsing electromagnetic fields, such as those used to potentiate the healing of non-unions, to speed healing of stress fractures. In the first trial, the field coil was embedded in the cast to produce a magnetic field around the fracture. The unit was supposed to be used for a minimum of six weeks but, due to change in treatment policies resulting from a turnover in staff with Desert Shield, the units were only used for a few weeks. Eighteen trainees used the units in their casts, ten just had casts (the standard treatment) during the treatment period and thirty-one just had the standard treatment before the treatment period. There was no difference between number of days it took those numbers of the groups able to return to duty to do so. However, only two of the treated soldiers had MEB's while twenty of the controls did. The pilot program will continue as an unfunded study at Ft. Sill. The proposed work and new investigators were identified in the annual report to MDRC for this project dated 6 Nov. 1992. DTIC

THE AGING MILITARY AVIATOR: A REVIEW AND ANNOTATED BIBLIOGRAPHY Final Report
Lewis W. Stone Jan. 1993 48 p
(DA Proj. 3M1-62787-A-879)
(AD-A265341; USAARL-93-11) Avail: CASI HC A03/MF A01

Studies suggest that aging is another factor which may affect performance of military pilots. Although these aviators generally are better-educated and healthier than their age peers in the general population, they, too, are subject to insidiously deteriorating physiological and sensory systems, a slowly increasing likelihood of acute pathologies, and a general slowing with age - all within the age range of military pilots. Reductions in some parameters might be offset to some degree by experience and maturity; however, age-related changes and the effects therefrom vary more between individuals in any age group than between the groups themselves. The real problem, though, is that we still do not know what effect, if any, age-related changes have on performance of military aviators. Neither is there a concerted effort to provide the aging pilot with a coping strategy for the approaching situation. DTIC

FUNCTIONAL REASONING, EXPLANATION, AND ANALYSIS
B. H. Far (Japan Atomic Energy Research Inst., Tokai.) Jan. 1992 104 p
(DE92-526832; JAERI-M-91-225) Avail: CASI HC A06/MF A02

Functional Reasoning (FR) enables people to derive the purpose of objects and explain their functions, JAERI's 'Human Acts Simulation Program (HASP)', started from 1987, has the goal of developing programs of the underlying technologies for intelligent robots by imitating the intelligent behavior of humans. FR is considered a useful reasoning method in HASP and applied to understand function of tools and objects in the Toolbox Project. First, the results of the diverse FR researches within a variety of disciplines are reviewed and the common core and basic problems are identified. Then the qualitative function formation (QFF) technique is introduced. Some points are: extending the common qualitative models to include interactions and timing of events by defining temporal and dependency constraints, and binding it with the conventional qualitative simulation. Function concepts are defined as interpretations of either a persistence or an order in the sequence of states, using the trace of the qualitative state vector derived by qualitative simulation on the extended qualitative model. This offers solutions to some of the FR problems and leads to a method for generalization and comparison of functions of different objects. DOE

Psychophysical studies of the processes underlying spatial localization and their relationship to both lower and higher level processing were conducted. The spatial extent of position integration areas was measured and found to be adequate to account for the increase in separation discrimination thresholds with separation. The influence of the spatial frequency of embedded targets was investigated and found to be insignificant, as it had previously been found to be for isolated targets. The relationship between separation discrimination and object formation was investigated and a model of the process of object formation developed. Studies on how area is encoded were conducted and related to the model of object formation. DTIC

PERCEPTUAL RESPONSE TO VISUAL NOISE AND DISPLAY MEDIA Final Report, 1 Jul. 1992 - 30 Jun. 1993
Frank H. Durgin and Dennis R. Proffitt 30 Jun. 1993 15 p
(Grant NAG2-814)
(NASA-CR-193406; NAS 1.26:193406) Avail: CASI HC A03/MF A01

The present project was designed to follow up an earlier investigation in which perceptual adaptation in response to the use of Night Vision Goggles, or image intensification (I squared) systems, such as those employed in the military were studied. Our chief concern in the earlier studies was with the dynamic visual noise that is a byproduct of the I(sup 2) technology: under low light conditions, there is a great deal of 'snow' or sporadic 'twinkling' of pixels in the I(sup 2) display which is more salient as the ambient light levels are lower. Because prolonged exposure to static visual noise produces strong adaptation responses, we reasoned that the dynamic visual noise of I(sup 2) displays might have a similar effect, which could have implications for their long term use. However, in the series of experiments reported last year, no evidence at all of such aftereffects following extended exposure to I(sup 2) displays were found. This finding surprised us, and led us to propose the following studies: (1) an investigation of dynamic visual noise and its capacity to produce after effects; and (2) an investigation of the perceptual consequences of characteristics of the display media. AVIATORS, AIR COMBAT, AND COMBAT STRESS: AN AIR F ORCE COMMANDER'S PRIMER Study Project
Mark K. Wells 22 Feb. 1993 47 p
(AD-A265083) Avail: CASI HC A03/MF A01

There is currently no interdisciplinary study which surveys the U.S. Air Force's philosophical and organizational responses to the problems of combat fatigue or psychological collapse during the history of air war. While stress and battle shock casualties are topics of concern inside the military medical community, the subjects receive little attention from contemporary aircrew, or, more importantly, among Air Force squadron and wing commanders. This study begins with a brief look at the human dimension of airpower, examines some of the characteristics of airmen, and reviews the risky nature of the air combat environment. It goes on to describe the impact of stress on airmen and covers the Air Force's historical responses to them. More than a simple survey, however, this monograph will make specific recommendations regarding the education and training of commanders, officers, and airmen so they will be equipped to deal realistically with the potential problem of stress related casualties. The distinctive hiss of radio 'noise' is familiar to all of us old enough to have listened to vintage A.M. radio shows and certainly to all those personnel who ever tried to 'pull in' a weak signal during a tour in military communications. Indeed, virtually since the birth of the telephone and radio and extending to today's sophisticated telecommunications designs, engineers have devoted prodigious efforts to eliminating or minimizing the effects of noise. In consequence, an entire discipline, known as linear filter theory, has evolved and is familiar to every electrical engineering and/or communications student, usually as one or a set of rather rigorous courses. By contrast, this paper is concerned with a nonlinear filtering process known as Stochastic Resonance (SR), research on which has been supported by the Physics Division of the Office of Naval Research (ONR) for several years and more recently by the Cognitive and Neural Sciences Division of the ONR. BASIC ATTRIBUTES TEST (BAT): OPERATIONAL PRE-IMPLEMENTATION ANALYSIS AND SCORE EQUATING Interim Report, Aug. 1991 - Apr. 1992

Thomas R. Carretta and Malcolm J. Ree May 1993 82 p
(AF Proj. 7719)
(AD-A265885; AL-TP-1993-0015) Avail: CASI HC A05/MF A01

The Air Force will implement a new pilot candidate selection system. Scores from a multiple aptitude test (Air Force Officer Qualifying Test or AFOQT), a computer-based test (Basic Attributes Test or BAT), and biographical information will be used to compute a pilot candidate selection composite score derived from an equation designed to indicate probability of success in undergraduate pilot training (UPT). The purpose of this study was to equate the experimental and operational tests. The pre-implementation equating was necessary for the following reasons: (1) to determine whether the tests measured the same psychological constructs, (2) to compare operational score distributions, and (3) to develop equating tables. Equating was required so that scores from operational tests could be used in proposed pilot candidate selection equations developed on the experimental tests of the BAT. Experimental and operational tests were administered to about 2,000 basic recruits. Analyses were performed at the test score and composite score level and several types of equatings were completed. Adjusted correlations between the experimental and operational BAT tests were acceptable and demonstrated measurement equivalence. Differences in the shapes of the distributions (i.e., skewness, kurtosis) were observed for several of the scores between the two forms. Several types of equatings (linear, equipercentile, smoothed equipercentile) were performed to develop conversion tables for use during implementation of operational tests. Scores will be renormed to the operational test metric and a new pilot candidate selection composite will be developed after a sufficient number of applicants have been tested and have completed UPT. MASS PROPERTIES TEST PROCEDURE FOR MANIKIN HEADFORMS AND HELMET SYSTEMS Final Report

Jeffrey M. Thornton and David J. Zaborowski (KR Systems, Inc., Warminster, PA.) Oct. 1992 47 p

(AD-A265654; NAWCADWAR-92092-60) Avail: CASI HC A03/MF A01

The mathematical modeling and comparison of manikin headforms and helmet systems requires that the mass properties be accurately determined. The specific properties that must be known are the weight, center of gravity location, magnitudes of the principal moments of inertia and orientation of the principal axes. This data is compared to the specifications of a specific program and also provides insight into issues such as helmet comfort/fit, fatigue and head accelerations/neck forces during ejection or emergency landings. The Mass Properties (M.P.) System and associated software, provide a relatively simple method for measuring these mass properties. This document is intended for use by persons responsible for operating the M.P. System. Included in this report are theoretical calculations, a description of materials required, and step-by-step procedures for system set-up, calibration and determination of weight, center of gravity, and magnitude and orientation of the principal mass moments of inertia. HEAD AND FACE ANTHROPOMETRY OF ADULT US CIVILIANS Final Report

Joseph W. Young Jul. 1993 43 p

(DOT/FAA/AM-93/10) Avail: CASI HC A03/MF A01

A total of 17 traditional and 5 new head and facial dimensions from a random, composite U.S. female and male civilian population measured over a period of 30 years are presented. The 5 new measurements, identified to describe specific anatomical relationships of the face, can have a direct influence on equipment design concepts. The survey population includes 376 (195 females and 172 males) adult subjects in the age range of 17 through 69 years representing a predominantly high ratio of Caucasian subjects to other ethnic origin subjects. The data summary format is specifically intended for basic design concept use. These dimensions describe essential anatomical characteristics for use as basic design criteria in the development of protective equipment for the head and face. Because of the lack of standardization of anatomical and anthropometrical terminology, a thesaurus of selected anatomical and anthropometrical terms, specific to descriptive labels used, is provided as a cross reference for anthropometrical dimensions. STATISTICAL ANALYSIS OF ENVIRONMENTAL VARIABILITY WITHIN THE CELSS BREADBOARD PROJECT'S BIOMASS PRODUCTION CHAMBER

G. W. Stutte, P. V. Chetirkin, C. L. Mackowiak, and R. E. Fortson Feb. 1993 39 p

(Contract NAS10-11624)

(NASA-TM-109188; NAS 1.15:109188; REV-399) Avail: CASI HC A03/MF A01

Variability in the aerial and root environments of NASA's Breadboard Project's Biomass Production Chamber (BPC) was determined. Data from two lettuce and two potato growouts were utilized. One growout of each crop was conducted prior to separating the upper and lower chambers; the other was subsequent to separation. There were little or no differences in pH, EC, or solution temperature between the upper and lower chamber or within a chamber. Variation in the aerial environment within a chamber was two to three times greater than variation between chambers for air temperature, relative humidity, and PPF. High variability in air velocity, relative to tray position, was observed. Separating the BPC had no effect on PPF, air velocity, solution temperature, pH, or EC. Separation reduced the gradient in air temperature and relative humidity between the upper and lower chambers, but increased the variability within a chamber. Variation between upper and lower chambers was within 5 percent of environmental set-points and of little or no physiological significance. In contrast, the variability within a chamber limits the capability of the BPC to generate statistically reliable data from individual tray treatments at this time. Author (revised)

CORRELATION OF HGU-56/P AIRCREW HELMET FITTING WITH HEAD ANTHROPOMETRIC MEASUREMENTS Final Report

James E. Bruckart, Kevin T. Mason, Samuel G. Shannon, William E. McLean, and Steven P. Pacquette Feb. 1993 31 p

(DA Proj. 3M1-62787-A-879)

(AD-A264988; USAARL-93-14) Avail: CASI HC A03/MF A01

The U.S. Army is developing an Aircrew Integrated Helmet System to replace the current flight helmets. The HGU-56/P flight helmet is proposed in six sizes with a new fitting method based on a nonstandard measure of the aviator head length. Standard anthropometric head measurements and the Gentex Corporation fitting method for the HGU-56/P flight helmet are evaluated to determine the applicability of the fitting method and distribution of helmet sizes required to fit the U.S. Army aviator population. Two hundred forty-two volunteer aviators had standard anthropometric measurements of their heads. Each was fitted with an HGU-561P flight helmet in their recommended size) and a helmet one size larger and one size smaller than recommended. ANVIS compatibility with each helmet was tested for a subset of the subjects. DTIC

ALLOWABLE EXPOSURE LIMITS FOR CARBON DIOXIDE DURING EXTRAVEHICULAR ACTIVITY

Andrew J. Seter Apr. 1993 42 p

(RTOP 506-71-00)

(NASA-TM-103832; A-91045; NAS 1.15:103832) Avail: CASI HC A03/MF A01

The intent was to review the research pertaining to human exposure to carbon dioxide (CO2) and to recommend allowable exposure limits for extravehicular activity (EVA). Respiratory, renal, and gastrointestinal systems may be adversely affected by chronic low dose CO2 exposure. Ventilation was increased 15 percent with 1 percent CO2 and 50 percent with 2 percent CO2. Chronic exposure to less than 2 percent CO2 led to 20 day cycles of uncompensated and compensated respiratory acidosis. Acid-base changes were small. Histopathologic changes in guinea pig lungs have been noted with long term exposure to 1 percent CO2. No changes were seen with exposure to 0.5 percent CO2. Cycling of bone calcium stores with associated changes in blood and urinary calcium levels occurs with long term CO2 exposure. Histologic changes in bone have been noted in guinea pigs exposed to 1 percent CO2. Renal calcification has been noted in guinea pigs with exposure to as low as 0.5 percent CO2. An increase in gastric acidity was noted in subjects with long term exposure to 1 percent CO2. Cardiovascular and neurologic function were largely unaffected. A decrease in the incidence of respiratory, renal, and gastrointestinal disease was noted in submariners coincident with a decrease in ambient CO2 from 1.2 percent to 0.8-0.9 percent. Oxygen (O2) and CO2 stimulate respiration independently and cumulatively. The addition of CO2 to high dose O2 led to the faster onset of seizure activity in mice. Experiments evaluating the physiologic responses to intermittent, repetitive exposures to low dose CO2 and 100 percent O2 mixtures should be performed. A reduction in the current NASA standard for CO2 exposure during EVA of 1 percent (7.6 mmHg) for nominal and 2 percent (15.2 mmHg) for heavy exertion to 0.5 percent (3.8 mmHg) for nominal and 1 percent (7.6 mmHg) for heavy exertion may be prudent. At a minimum, the current NASA standard should not be liberalized. Author (revised)

TEACHING HIGH-PERFORMANCE SKILLS USING ABOVE-REAL-TIME TRAINING

Dutch Guckenberger, Kevin C. Uliano (University of Central Florida, Orlando.), and Norman E. Lane (University of Central Florida, Orlando.) Aug. 1993 60 p Sponsored by NASA. Dryden Flight Research Facility

(Grant NAG2-750; RTOP 505-68-00)
(NASA-CR-4528; H-1919; NAS 1.26:4528) Avail: CASI HC A04/MF A01

The above real-time training (ARTT) concept is an approach to teaching high-performance skills. ARTT refers to a training paradigm that places the operator in a simulated environment that functions at faster than normal time. It represents a departure from the intuitive, but not often supported, feeling that the best practice is determined by the training environment with the highest fidelity. This approach is hypothesized to provide greater 'transfer value' per simulation trial, by incorporating training techniques and instructional features into the simulator. Two related experiments are discussed. In the first, 25 naive male subjects performed three tank gunnery tasks on a simulator under varying levels of time acceleration (i.e., 1.0x, 1.6x, 2.0x, sequential, and mixed). They were then transferred to a standard (1.0x) condition for testing. Every accelerated condition or combination of conditions produced better training and transfer than the standard condition. Most effective was the presentation of trials at 1.0x, 1.6x, and 2.0x in a random order during training. Overall, the best ARTT group scored about 50 percent higher and trained in 25 percent less time compared to the real-time control group. In the second experiment, 24 mission-capable F-16 pilots performed three tasks on a part-task F-16A flight simulator under varying levels of time compression (i.e., 1.0x, 1.5x, 2.0x, and random). All subjects were then tested in a real-time environment. The emergency procedure (EP) task results showed increased accuracy for the ARTT groups. In testing (transfer), the ARTT groups not only performed the EP more accurately, but dealt with a simultaneous enemy significantly better than a real-time control group. Although the findings on an air combat maneuvering task and stern conversion task were mixed, most measures indicated that the ARTT groups performed better and faster than a real-time control group. Other implications for ARTT are discussed along with future research directions. Author (revised)

A COMPARISON OF HEAD-UP AND HEAD-DOWN DISPLAY FORMATS DURING INSTRUMENT FLYING TASKS Final Report, Mar. 1991 - Oct. 1992
Thomas C. Hughes, John A. Hassoun, and James M. Barnaba Nov. 1992 109 p
(AD-A266140; ASC-TR-93-5003) Avail: CASI HC A06/MF A02

In March 1989, the Chief of Staff of the Air Force issued a study regarding the status of instrument flying within the Air Force. In that report, specific recommendations were presented, first of which was the necessity to develop a standardized HUD format suitable for use as a primary flight reference. Since that time a HUD symbology set was proposed and adopted conditional upon final validation as a primary flight reference. The present report documents the simulation phase of the validation process in which a total of 38 pilots participated. The validation of the symbology set consisted of a comparison of pilot performance data during three instrument flight tasks (1) Unusual Attitude Recovery, (2) Precision Approach, and (3) Precision Instrument Maneuvering. Results indicated that pilot data were significantly improved while flying with the HUD during the Precision Approach and Instrument Maneuvering tasks. During the Unusual Attitude Recovery tasks, no significant differences were demonstrated; however, the HUD symbology showed a trend toward faster reaction times, particularly for the nose low recoveries. Based on these results, the CSEF recommended initiation of the follow-on flight test phase of the validation process. DTIC

ACCURACY AND REPEATABILITY OF THE STANDARD AUTOMATED MASS PROPERTIES MEASUREMENT SYSTEM Interim Report, Dec. 1991 - Sep. 1992
Brian P. Self, Eric K. Spittle, Ints Kaleps, and Christopher Albery Sep. 1992 54 p
(AF Proj. 7231)
(AD-A265897; AL-TR-1992-0137) Avail: CASI HC A04/MF A01

The injury potential to pilots may be significantly affected by the inertial properties of helmet-mounted equipment. In order to accurately assess the effects of such equipment, reliable measurements of mass, center of mass, and mass moments of inertia must be obtained. The Manikin Testing Laboratory at the Armstrong Laboratory has developed the Standard Automated Mass Properties (STAMP) system to experimentally determine the inertial properties of various objects. It is necessary to quantitatively determine the accuracy and repeatability of measurements obtained by the STAMP system to confidently use these values in analytical models, in correlations between observed empirical response and the inertial properties of head-mounted equipment, and in determining compliance with inertial properties specifications of new helmet-mounted systems. This report covers the second year of research relating to the development of closed-loop long-term life support systems. Emphasis was directed toward concentrating on the development of dynamic simulation techniques and software and on performing a thermodynamic systems analysis in an effort to begin optimizing the system needed for water purification. Four appendices are attached. The first covers the ASPEN modeling of the closed loop Environmental Control Life Support System (ECLSS) and its thermodynamic analysis. The second is a report on the dynamic model development for water regulation in humans. The third regards the development of an interactive computer-based model for determining exercise limitations. The fourth attachment is an estimate of the second law thermodynamic efficiency of the various units comprising an ECLSS. For individual titles, see N94-12366 through N94-12369.

[SYSTEMS ANALYSIS OF A CLOSED LOOP ECLSS USING THE ASPEN SIMULATION TOOL. THERMODYNAMIC EFFICIENCY ANALYSIS OF ECLSS COMPONENTS] M.S. Thesis
Sharmista Chatterjee *In its* Space Life Support Engineering Program 30 Jun. 1993 135 p (For primary document see N94-12365 01-54)
Avail: CASI HC A07/MF A03

Our first goal in this project was to perform a systems analysis of a closed loop Environmental Control Life Support System (ECLSS). This pertains to the development of a model of an existing real system from which to assess the state or performance of the existing system. Systems analysis is applied to conceptual models obtained from a system design effort. For our modelling purposes we used a simulator tool called ASPEN (Advanced System for Process Engineering). Our second goal was to evaluate the thermodynamic efficiency of the different components comprising an ECLSS. Use is made of the second law of thermodynamics to determine the amount of irreversibility of energy loss of each component. This will aid design scientists in selecting the components generating the least entropy, as our penultimate goal is to keep the entropy generation of the whole system at a minimum. The water of the human body can be categorized as existing in two main compartments: intracellular water and extracellular water. The intracellular water consists of all the water within the cells and constitutes over half of the total body water. Since red blood cells are surrounded by plasma, and all other cells are surrounded by interstitial fluid, the intracellular compartment has been subdivided to represent these two cell types. The extracellular water, which includes all of the fluid outside of the cells, can be further subdivided into compartments which represent the interstitial fluid, circulating blood plasma, lymph, and transcellular water. The interstitial fluid surrounds cells outside of the vascular system whereas plasma is contained within the blood vessels. Avascular tissues such as dense connective tissue and cartilage contain interstitial water which slowly equilibrates with tracers used to determine extracellular fluid volume. For this reason, additional compartments are sometimes used to represent these avascular tissues. The average size of each compartment, in terms of percent body weight, has been determined for adult males and females. These compartments and the forces which cause flow between them are presented. The kidneys, a main compartment, receive about 25 percent of the cardiac output and filters out a fluid similar to plasma. The composition of this filtered fluid changes as it flows through the kidney tubules since compounds are continually being secreted and reabsorbed. Through this mechanism, the kidneys eliminate wastes while conserving body water, electrolytes, and metabolites. Since sodium accounts for over 90 percent of the cations in the extracellular fluid, and the number of cations is balanced by the number of anions, considering the renal handling sodium and water only should sufficiently describe the relationship between the plasma compartment and kidneys. A kidney function model is presented which has been adapted from a previous model of normal renal function in man. To test the validity of the proposed kidney model, results predicted by the model will be compared to actual data involving injected or ingested fluids and subsequent urine flow rates. Comparison of the model simulation to actual data following the ingestion of 1 liter of water is shown. The model simulation is also shown with actual data following the intravenous infusion of hypertonic saline. Derived from text

MODIFICATIONS TO AN INTERACTIVE MODEL OF THE HUMAN BODY DURING EXERCISE: WITH SPECIAL EMPHASIS ON THERMOREGULATION M.S. Thesis

Megan Kay Scherb *In its* Space Life Support Engineering Program 64 p(SEE N94-12365 01-54) 30 Jun. 1993 (For primary document see N94-12365 01-54)

Avail: CASI HC A04/MF A03

Since 1988 an interactive computer model of the human body during exercise has been under development by a number of undergraduate students in the Department of Chemical Engineering at Iowa State University. The program, written under the direction of Dr. Richard C. Seagrave, uses physical characteristics of the user, environmental conditions and activity information to predict the onset of hypothermia, hyperthermia, dehydration, or exhaustion for various levels and durations of a specified exercise. The program however, was severely limited in predicting the onset of dehydration due to the lack of sophistication with which the program predicts sweat rate and its relationship to sensible water loss, degree of acclimatization, and level of physical training. Additionally, it was not known whether sweat rate also depended on age and gender. For these reasons, the goal of this creative component was to modify the program in the above mentioned areas by applying known information and empirical relationships from literature. Furthermore, a secondary goal was to improve the consistency with which the program was written by modifying user input statements and improving the efficiency and logic of the program calculations. [AN ESTIMATE OF THE SECOND LAW THERMODYNAMIC EFFICIENCY OF THE VARIOUS UNITS COMPRISING AN ENVIRONMENTAL CONTROL AND LIFE SUPPORT SYSTEM (ECLSS)]

Sharmista Chatterjee and Richard C. Seagrave *In its* Space Life Support Engineering Program 12 p(SEE N94-12365 01-54) 30 Jun. 1993 Presented at the International Conference on Environmental Science, Jul. 1993 (For primary document see N94-12365 01-54)

Avail: CASI HC A03/MF A03

The objective of this paper is to present an estimate of the second law thermodynamic efficiency of the various units comprising an Environmental Control and Life Support System (ECLSS). The technique adopted here is based on an evaluation of the 'lost work' within each functional unit of the subsystem. Pertinent information for our analysis is obtained from a user interactive integrated model of an ECLSS. The model was developed using ASPEN. A potential benefit of this analysis is the identification of subsystems with high entropy generation as the most likely candidates for engineering improvements. This work has been motivated by the fact that the design objective for a long term mission should be the evaluation of existing ECLSS technologies not only the basis of the quantity of work needed for or obtained from each subsystem but also on the quality of work. In a previous study Brandhorst showed that the power consumption for partially closed and completely closed regenerable life support systems was estimated as 3.5 kw/individual and 10-12 kw/individual respectively. With the increasing cost and scarcity of energy resources, our attention is drawn to evaluate the existing ECLSS technologies on the basis of their energy efficiency. In general the first law efficiency of a system is usually greater than 50 percent. From literature, the second law efficiency is usually about 10 percent. The estimation of second law efficiency of the system indicates the percentage of energy degraded as irreversibilities within the process. This estimate offers more room for improvement in the design of equipment. From another perspective, our objective is to keep the total entropy production of a life support system as low as possible and still ensure a positive entropy gradient between the system and the surroundings. The reason for doing so is as the entropy production of the system increases, the entropy gradient between the system and the surroundings decreases, and the system will gradually approach equilibrium with the surroundings until it reaches the point where the entropy gradient is zero. At this point no work can be extracted from the system. This is called the 'dead state' of the system. Author

[PREPARING FOR THE INITIAL OBSERVATIONS OF THE TARGETED SEARCH AND THE SKY SURVEY SYSTEMS] Final Report

Michael M. Davis 20 Jan. 1993 2 p
(Grant NAG2-696)
(NASA-CR-193644; NAS 1.26:193644) Avail: CASI HC A01/MF A01

During this period, the SETI project prepared for the initial observations with both the Targeted Search and Sky Survey systems. I am nominally a member of the Targeted Search team, but participated actively in both parts of the project. My activities were concentrated primarily in three areas: coordination with Arecibo Observatory in preparation for the initial observations on October 12, 1992; development of a design concept for confirming observations; and participation (at JPL) in a design review of the rf system. Multidisciplinary Design Optimization refers to some combination of disciplinary analyses, sensitivity analysis, and optimization techniques used to design complex engineering systems. The ultimate objective of this research at NASA Langley Research Center is to help the US industry reduce the costs associated with development, manufacturing, and maintenance of aerospace vehicles while improving system performance. This report reviews progress towards this objective and highlights topics for future research. Aerospace design problems selected from the author's research illustrate strengths and weaknesses in existing multidisciplinary optimization techniques. The techniques discussed include multiobjective optimization, global sensitivity equations and sequential linear programming. Author

The Tenth Army Conference on Applied Mathematics and Computing was held at the U.S. Military Academy, West Point, on 16-19 June 1992. The 1992 conference was attend by more than 80 scientists and engineers representing various Army agencies and academia. The meeting featured seven invited speakers. These general talks covered several topics of current interest, including natural language processing, wavelet analysis, variational methods, small sample asymptotics, computational fluid dynamics, digital control programs, and parallel programming. The second part of the program consisted of special sessions on topics such as computational algebraic geometry, mathematical aspects of material sciences, scalability in high performance computing, and robust control and nonlinear systems. CAREER INFORMATION IN THE MATHEMATICAL SCIENCES (CIMS) Annual Technical Progress Report

Andrew Sterrett May 1993 16 p Presented at the CBMS Council Meeting, Washington, DC, 1-2 May 1993
(Contract DE-FG02-93ER-75840)
(DE93-013780; DOE/ER-75840/1) Avail: CASI HC A03/MF A01

In Nov. 1992, a CBMS Steering Committee for Career Information was appointed by the CBMS Council. An informal meeting of those members in attendance at the Annual Meeting of the MAA and the AMS was held in Jan. 1993. The first meeting was held on 1-2 May in Washington, DC in conjunction with the CBMS Council meeting. Information on existing career materials was provided to the Council at that time and Council reactions were obtained. These reactions, along with reviews of material by students, faculty members, and counselors, were used by the Steering Committee to plan specific activities for the next 6-18 months. Three initiatives were given high priority: To produce and widely disseminate an annotated bibliography of career information relevant to the mathematical sciences; to remedy the lack of messages to junior high school students, parents, teachers and counselors on the importance of mathematics in finding good jobs in a technological society; and to encourage women and minorities to take all the mathematics that they can and to consider careers in which mathematics plays an important role. RADIATION HARDENED NONVOLATILE MEMORY FOR SPACE AND STRATEGIC APPLICATIONS

M. Jacunski (Westinghouse Electric Corp., Linthicum Heights, MD.), D. Williams (Westinghouse Electric Corp., Linthicum Heights, MD.), D. Adams (Westinghouse Electric Corp., Linthicum Heights, MD.), R. Bishop (Westinghouse Electric Corp., Linthicum Heights, MD.), J. Murray, J. Jakubczak, and J. Rodriguez 1992 6 p Presented at the Government Microcircuit Applications Conference: Microelectronics in the New World Order, Las Vegas, NV, 9-12 Nov. 1992
(Contract DE-AC04-76DP-00789)
(DE93-000746; SAND-92-2043C; CONF-921188-1) Avail: CASI HC A02/MF A01 (US Sales Only)

As system complexity increases, so too do the nonvolatile memory needs for the storage of data and microcode. Electrically erasable programmatic read only memories (EEPROM's) are also the frequent choice for applications which in the past have been satisfied by read only memories (ROM's). For system engineers. the ability to electrically reprogram a system module on the fly is indispensable. Two different modes of operation must be considered when evaluating the radiation hardness of EEPROMS. For ROM applications, little if any programming occurs in the radiation environment, and only the read mode need be considered. The chip must (1) retain the information throughout the irradiation, and (2) maintain the functionality of the peripheral circuits necessary for reading the data. For nonvolatile SRAM type applications, the chip must also function in the write mode during the exposure. Unfortunately, commercial EEPROM's have not kept pace with the aggressive radiation specifications of many space and strategic systems. Several studies indicate that the most popular commercial floating gate (FG) technologies manufactured by Xicor, Atmel, and Seeq fail after total doses of just 4 to 18 Krad(Si) in the read mode and after less than 5 Krad(Si) in the write mode. In fact, the very nature of the commercial FG technology has been shown to be limited to a hardness of less than 100 Krad(Si). A 64K EEPROM designed by Sandia National Laboratories (SNL) and manufactured by Westinghouse Electric Corporation (WEC) is described. It is pin for pin compatible with commercial 64K EEPROMS. The nonvolatile memory clement is fabricated with a silicon/oxide/ nitride/oxide/semiconductor (SONOS) technology for which 1 Mrad(Si) hardness was demonstrated. In addition, the CMOS peripheral circuitry was hardened using techniques developed for Westinghouse's radiation hardened gate array products. DOE

FINITE STATE MACHINE MICROARCHITECTURE TRANSFORMATIONS DESCRIBED WITH RELATIONAL ALGEBRA

A. J. W. M. tenBerg Oct. 1992 43 p
(Memo-INF-92-63; ETN-93-94320) Copyright Avail: CASI HC A03/MF A01

A number of microarchitecture alternatives for the controlpath implementation of finite state machines by means of relational algebra are described. Relational algebra, developed for database design, can also be applied for hardware microarchitecture design. Relational algebra makes it easy to prove that the set of hardware functions in a decomposition perform a functional behavior equivalent to that of the canonical function. It describes operations on tables that represent the hardware functions. Such decompositions represent microarchitectures of the finite state machines in a direct way. Different finite state machine microarchitectures, formerly viewed as separate alternatives, are derived from each other by transformations described by short operation sequences. The traditionally algorithmically described Mealy to Moore machine transformation can be described in only a few operations with relational algebra. ESA

A PROOF-OF-CONCEPT IMPLEMENTATION OF PERSISTENCE IN A HIERARCHICAL STORAGE SYSTEM

R. Grossman, Xiao Qin, and D. Lifka 1992 6 p Presented at the 12th IEEE Symposium on Mass Storage Systems, Monterey, CA, 25 Apr. 1993
(Contract W-31-109-eng-38)
(DE93-009959; ANL-HEP-CP-92-100; CONF-930461-2) Avail: CASI HC A02/MF A01

The concept of providing transparent access to a collection of files in a mass storage system is a familiar one. The goal of this project was to investigate the feasibility of providing similar access to a collection of persistent, complex objects. We describe an architecture for interfacing a persistent store of complex objects to a hierarchical storage system. Persistent object stores support the uniform creation, storage, and access of complex objects, regardless of their lifetimes. In other words, a mechanism is provided so that persistent objects outlive the processes which create them and can be accessed in a uniform manner by other processes. We validated this architecture by implementing a proof-of-concept system and testing the system on two stores of data. These tests indicate that this architecture supports the creation, storage and access of very large persistent object stores. DOE

DISTRIBUTED SIMULATION USING A REAL-TIME SHARED MEMORY NETWORK

Donald L. Simon, Duane L. Mattern (Sverdrup Technology, Inc., Bay Saint Louis, MS.), Edmond Wong, and Jeffrey L. Musgrave Jul. 1993 20 p
(DA Proj. 1L1-61102-AH-45; RTOP 505-62-50)
(NASA-TM-106239; E-7969; NAS 1.15:106239; AVSCOM-TR-92-C-020)
Avail: CASI HC A03/MF A01

The Advanced Control Technology Branch of the NASA Lewis Research Center performs research in the area of advanced digital controls for aeronautic and space propulsion systems. This work requires the real-time implementation of both control software and complex dynamical models of the propulsion system. We are implementing these systems in a distributed, multi-vendor computer environment. Therefore, a need exists for real-time communication and synchronization between the distributed multi-vendor computers. A shared memory network is a potential solution which offers several advantages over other real-time communication approaches. A candidate shared memory network was tested for basic performance. The shared memory network was then used to implement a distributed simulation of a ramjet engine. The accuracy and execution time of the distributed simulation was measured and compared to the performance of the non-partitioned simulation. The ease of partitioning the simulation, the minimal time required to develop for communication between the processors and the resulting execution time all indicate that the shared memory network is a real-time communication technique worthy of serious consideration.

ALLEVIATING MEMORY CONTENTION IN MATRIX COMPUTATIONS ON LARGE-SCALE SHARED-MEMORY MULTIPROCESSORS
Ricardo Bianchini, Mark E. Crovella, Leonidas I. Kontothanassis, and Thomas J. LeBlanc Apr. 1993 24 p
(Contract N00014-92-J-1801; NSF CDS-88-22724; ARPA Order 8930)
(AD-A265009; TR-449) Avail: CASI HC A03/MF A01

Memory contention can be a major source of overhead in large-scale shared-memory multiprocessors. There are many hardware solutions, but they are often complex and expensive, so software solutions are an attractive alternative. This paper evaluates one solution, block-column allocation, which is very effective at reducing memory contention for a large class of SPMD (Single-Program-Multiple-Data) programs, and can be implemented easily by the compiler. We first quantify the impact of memory contention on performance by simulating the execution of several application kernels on a large-scale multiprocessor. Our simulation results confirm that memory contention is widespread on large-scale machines; our applications suggest that contention is usually caused by synchronized access to a range of addresses (rather than to a single address). We show that block-column allocation can nearly eliminate this source of memory contention. As our main contribution, we compare block-column allocation to row-major allocation and logarithmic broadcasting. Our analysis demonstrates the clear superiority of block-column allocation over row-major allocation in the presence of memory contention. DTIC

GALLIUM ARSENIDE DYNAMIC RANDOM ACCESS MEMORY SUPPORT CIRCUITRY M.S. Thesis
Michael A. Morris Mar. 1993 528 p
(AD-A265176) Avail: CASI HC A23/MF A04

This thesis presents the design and layout of a Gallium Arsenide (GaAs) Dynamic Random Access Memory (DRAM) array of eight four-bit words including refresh circuitry. In the last several years, there has been significant research investigating the possibilities of producing fast, low power, and high density DRAM's using GaAs. Thus far, this research has yielded success on a limited basis using special materials and fabrication techniques. This design, tested and simulated using HSPICE, supports a memory access time of approximately three nanoseconds, faster than present commercial Static Random Access Memory (SRAM). The logic circuits are designed using GaAs enhancement-mode and depletion-mode (E/D) metal semiconductor field-effect transistors (MESFET's). Charge storage is facilitated by a single GaAs MESFET connected to a parallel plate capacitor and the required minimum time between refresh is approximately three milliseconds. Power consumption is acceptable and fabrication by Vitesse Semiconductor Corporation using the HGaAs3 process is in progress. The design techniques, power consumption, and timing are discussed and demonstrated for the basic logic circuits and the memory array read, write, and refresh cycles. A significant increase in DRAM memory bandwidth is gained narrowing the memory bandwidth differential between primary memory and the processor. DTIC

COGNITIVE ENGINEERING MODELS: A PREREQUISITE TO THE DESIGN OF HUMAN-COMPUTER INTERACTION IN COMPLEX DYNAMIC SYSTEMS Final Technical Report, 1 Jul. 1990 - 30 Nov. 1993
Christine M. Mitchell Jun. 1993 22 p
(Grant NAG9-422)
(NASA-CR-193472; NAS 1.26:193472) Avail: CASI HC A03/MF A01

This chapter examines a class of human-computer interaction applications, specifically the design of human-computer interaction for the operators of complex systems. Such systems include space systems (e.g., manned systems such as the Shuttle or space station, and unmanned systems such as NASA scientific satellites), aviation systems (e.g., the flight deck of 'glass cockpit' airplanes or air traffic control) and industrial systems (e.g., power plants, telephone networks, and sophisticated, e.g., 'lights out,' manufacturing facilities). The main body of human-computer interaction (HCI) research complements but does not directly address the primary issues involved in human-computer interaction design for operators of complex systems. Interfaces to complex systems are somewhat special. The 'user' in such systems - i.e., the human operator responsible for safe and effective system operation - is highly skilled, someone who in human-machine systems engineering is sometimes characterized as 'well trained, well motivated'. The 'job' or task context is paramount and, thus, human-computer interaction is subordinate to human job interaction. The design of human interaction with complex systems, i.e., the design of human job interaction, is sometimes called cognitive engineering. Author (revised)

BUNDLE EVENT STRUCTURES: A NON-INTERLEAVING SEMANTICS FOR LOTOS
Rom Langerak 11 Oct. 1992 20 p Sponsored in part by EEC
(Memo-INF-92-73; TIOS-92/30; ETN-93-94321) Copyright Avail: CASI HC A03/MF A01

The semantic model of bundle event structures, using a so called bundle set instead of a causality or flow relation, are defined. Several laws for set equivalence are presented. A representation called clean bundle event structures and an algorithm to turn any bundle event structure into a clean one are provided. Bundle event structures have an attractive graphical representation; the analysis is facilitated by providing several equivalence laws. Like in flow and stable event structures, events can be enabled in different ways. There are no self conflicting events like in flow event structures. Impossible events that can never happen but can always be removed are considered. A bundle event structure semantics is given for a Basic LOTOS subset containing all operators except disabling and process instantiation. This semantics is proven correct with respect to a simple event transition system. ESA

AN OBJECT-ORIENTED MODEL FOR EXTENSIBLE CONCURRENT SYSTEMS: THE COMPOSITION-FILTERS APPROACH
Lodewijk Bergmans, Mehmet Aksit, Ken Wakita, and Akinori Yonezawa (Tokyo Univ., Japan.) Dec. 1992 45 p
(Memo-INF-92-87; ETN-93-94325) Copyright Avail: CASI HC A03/MF A01

A new language model based on the concept of object composition filters is proposed. A composition filter is a modular extension to the conventional object model. It is able to express concurrency and synchronization mechanisms integrated with the concept of inheritance. The background and related work in the area of object oriented concurrent programming and synchronization are described. Inheritance anomalies and requirements of concurrent object oriented systems are studied. The mechanisms to support extensible concurrency and synchronization using composition filters are presented. Examples to demonstrate the capabilities of the proposed mechanisms to solve some well known synchronization problems are included. Examples in four different categories were chosen: process communication and coordination, implementation of functions, scheduling, and resource management. The composition filters model is evaluated with respect to the requirements. ESA

A CORRECT AND EFFICIENT INTERFACE FOR LOGICAL QUERY LANGUAGES WITH COMPLEX OBJECTS
Marcel Holsheimer, Rolf A. deBy, and Hassan Ait-Kaci Jan. 1993 14 p
(Memo-INF-93-01; ETN-93-94326) Copyright Avail: CASI HC A03/MF A01

A formal design for a logical query language using psi terms as data structures to interact effectively and efficiently with a relational database is described. The structure of psi terms provides an adequate representation for so called complex objects. They generalize conventional terms used in

logic programming: they are typed attributed structures, ordered thanks to a subtype ordering. Unification of psi terms is an effective means for integrating multiple inheritance and partial information into a deduction process. A compact database representation for psi terms, representing part of the subtyping relation in the database as well is defined. A retrieval algorithm based on an abstract interpretation of the psi term unification process is presented and its formal correctness is proven. This algorithm is efficient in that it incrementally retrieves only additional facts that are actually needed by a query, and never retrieves the same fact twice.

PANACEA USER'S MANUAL FOR PANACEA VERSION 2.0
S. A. Brown and D. Braddy Jan. 1993 99 p Revised
(Contract W-7405-eng-48)
(DE93-012502; LLNL-M-276-Rev-2) Avail: CASI HC A05/MF A02

A numerical simulation code is fundamentally a device to solve an initial value problem. Very often these programs are written starting with the routines that solve some system of equations. Unless care is taken to formulate these routines with regard to a host of issues (e.g., data flow), it can be very awkward to set up a problem or to look at the answers that the code returns. Furthermore, it can be nearly impossible to take advantage of some of the excellent work that various groups have done (e.g., equation solver packages) because the data flow and structuring issues have not been given sufficient attention in the program design stages. One way to avoid some of these difficulties is to write the data flow controls, the I/O mechanisms, and the database manager first. With these parts in place, there is a great deal of guidance for building the parts of a simulation code that deals with the specific set of equations to be solved; thus initial value data is input, and the solution is written out clearly and conveniently. Furthermore, this approach provides a basis for defining some conventions to allow the sharing of simulation modules. It also helps isolate the machine dependencies of a code in a very few places, which greatly enhances the portability of the code. PANACEA is a library of routines built to address these issues. In essence, PANACEA attempts to embody all of the functionality of a numerical simulation code, which is generic to all simulation codes. It accomplishes this by implementing a model of the simulation as a system of services (routines), which are bound together with the simulation specific routines provided by the code developer. One useful result of this approach is that it effectively imposes a discipline for the development of simulation codes that promote shareability, portability, and inter-operability.

THE SUPER VECTORFIELD PACKAGE FOR REDUCE. VERSION 1.0
G. H. Marcel Roelofs Nov. 1992 21 p
(MEMO-1099; ETN-93-94312) Avail: CASI HC A03/MF A01

The super vectorfield package implements Z(sub 2) graded vectorfields and their action on Z(sub 2) graded functions in local coordinates in REDUCE. It can be used for the computation of symmetries and prolongation structures of (supersymmetric) systems of partial differential equations. The package is based on a former package developed by other investigators. A short description of the local picture of a graded manifold and vectorfields on these graded manifolds is given. An implementation of the vectorfields as algebraic operators is presented. Two procedures for extending the number of variables of a vectorfield are included. Simplified procedures to implement the action of a vectorfield and for multiplying two graded expressions are shown.

N94-10267# Lawrence Livermore National Lab., CA.
SURVEY TO DETERMINE THE VALUE OF DYNA
J. W. Walter and D. Bellshaw Jan. 1993 36 p
(Contract W-7405-eng-48)
(DE93-012390; UCRL-ID-112607) Avail: CASI HC A03/MF A01

This report presents the value of the DYNA software program to US Industry. The software conducts dynamic finite element analysis tailored specifically to simulating high energy impacts, such as car crashes or aircraft collisions with birds. DYNA is available at nearly zero cost to the public in two-dimensional (DYNA2D) and three-dimensional versions (DYNA3D). DYNA has had a major impact on US industry. Measuring this impact using conventional approaches, such as profitability or revenue size, does not apply to DYNA. A new approach is needed to estimate DYNA's value to US industry. Our challenge was two fold: (1) to develop a methodology for valuing technology transferred to the public domain; and (2) to apply this methodology to DYNA. We accomplished the evaluation task by using indirect measurements of value. These indicators encompassed three broad categories, answering three key questions: (1) Use of DYNA and 'DYNA-like' codes--Are companies, academic institutions, government agencies actually using DYNA and codes like it? (2) Savings generated from using these codes--Is the use of DYNA and codes like it creating a positive economic impact? and (3) Market size of all 'DYNA-like' codes--Has a commercial market developed for 'DYNA-like' codes? This study represents the results of interviews with people identified by Lawrence Livermore National Laboratory (LLNL) as users of DYNA. Some of the people surveyed for this study do not use DYNA. They rely upon other dynamic finite element analysis codes. We refer to these individuals as users of 'DYNA-like' codes or 'codes like DYNA.' Several of the 'DYNA-like' codes used DYNA as their core. These codes are descendants of DYNA.

VIRTUAL SOUND FOR VIRTUAL REALITY
Meera M. Blattner and Albert L. Papp, III Feb. 1993 7 p Presented at the 1993 Virtual Reality System, New York, NY, 15-17 Mar. 1993
(Contract W-7405-eng-48)
(DE93-010519; UCRL-JC-112806; CONF-9303127-1) Avail: CASI HC A02/MF A01

The computational limitations of real-time interactive computing do not meet our requirements for producing realistic images for virtual reality in a convincing manner. Regardless of the real-time restrictions on virtual reality interfaces, the representations can be no better than the graphics. Computer graphics is still limited in its ability to generate complex objects such as landscapes and humans. Nevertheless, useful and convincing visualizations are made through a variety of techniques. The central theme of this article is that a similar situation is true with sound for virtual reality. It is beyond our ability to create interactive soundscapes that create a faithful reproduction of real world sounds, however, by choosing one's application carefully and using sound to enhance a display rather than only mimic real-world scenes, a very effective use of sound can be made.

This guide shows independent operational evaluators and operational testers how to measure the usability (or User Friendliness) of computer software components that require human interaction. It shows how to measure the effectiveness and efficiency of human interactions with the software components of any weapon, equipment, computer, or information mission area system. The methodology in the guide can be applied during any phase of the Acquisition Process. It also addresses the inherent trainability of software components. It covers interfaces, preparation of questionnaires and other data collection instruments, data analysis, and the development of Usability Profiles to describe all the software interfaces of a system. It contains lists of questionnaire and checklist items, and examples of questionnaires, used to gather data on User Friendliness and human factors (or MANPRINT).

[STUDIES AND SIMULATIONS OF THE DigiCipher SYSTEM]
Semiannual Status Report, 15 Dec. 1992 - 15 Jun. 1993
K. Sayood, Y. C. Chen, and G. Kipp 1993 65 p
(Grant NAG5-1612)
(NASA-CR-193470; NAS 1.26:193470) Avail: CASI HC A04/MF A01

During this period the development of simulators for the various high definition television (HDTV) systems proposed to the FCC was continued. The FCC has indicated that it wants the various proposers to collaborate on a single system. Based on all available information this system will look very much like the advanced digital television (ADTV) system with major contributions only from the DigiCipher system. The results of our simulations of the DigiCipher system are described. This simulator was tested using test sequences from the MPEG committee. The results are extrapolated to HDTV video sequences. Once again, some caveats are in order. The sequences used for testing the simulator and generating the results are those used for testing the MPEG algorithm. The sequences are of much lower resolution than the HDTV sequences would be, and therefore the extrapolations are not totally accurate. One would expect to get significantly higher compression in terms of bits per pixel with sequences that are of higher resolution. However, the simulator itself is a valid one, and should HDTV sequences become available, they could be used directly with the simulator. A brief overview of the DigiCipher system is given. Some coding results obtained using the simulator are looked at. These results are compared to those obtained using the ADTV system. These results are evaluated in the context of the CCSDS specifications and make some suggestions as to how the DigiCipher system could be implemented in the NASA network. Simulations such as the ones reported can be biased depending on the particular source sequence used. In order to get more complete information about the system one needs to obtain a reasonable set of models which mirror the various kinds of sources encountered during video coding. A set of models which can be used to effectively model the various possible scenarios is provided. As this is somewhat tangential to the other work reported, the results are included as an appendix. The purpose of this report is to provide a detailed survey of current recommended practices and measurement techniques for the development of reliable and safe software-based systems. This report is intended to assist the United States Nuclear Reaction Regulation (NRR) in determining the importance and maturity of the available techniques and in assessing the relevance of individual standards for application to instrumentation and control systems in nuclear power generating stations. Lawrence Livermore National Laboratory (LLNL) provides technical support for the Instrumentation and Control System Branch (ICSB) of NRR in advanced instrumentation and control systems, distributed digital systems, software reliability, and the application of verification and validation for the development of software. A SIMPLICIAL APPROACH TO INTEGER PROGRAMMING
Chuangyin Dang and Hans vanMaaren 1993 28 p
(Rept-93-06; ETN-93-94301) Copyright Avail: CASI HC A03/MF A01

An algorithm to find an integral point in a polytope is proposed. It is based on an integer labelling rule and a triangulation of the space. It is proved that the algorithm determines an integral point in a polytope from a certain class. Numerical tests show the efficiency of the algorithm. The basic idea of the algorithm is to subdivide R(to the nth power) into simplices with integral vertices and assign an integer to each point in R(to the nth power). ESA

MODEL-BASED RECOGNITION OF 3-D OBJECTS BY GEOMETRIC HASHING TECHNIQUE
M. Severcan (Middle East Technical Univ., Ankara, Turkey.) and H. Uzunalioglu (Middle East Technical Univ., Ankara, Turkey.) Sep. 1992 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-612916; IC-92/295) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

A model-based object recognition system is developed for recognition of polyhedral objects. The system consists of feature extraction, modeling, and matching stages. Linear features are used for object descriptions. Lines are obtained from edges using rotation transform. For modeling and recognition process, geometric hashing method is utilized. Each object is modeled using 2-D views taken from the viewpoints on the viewing sphere. A hidden line elimination algorithm is used to find these views from the wire frame model of the objects. The recognition experiments yielded satisfactory results. DOE

THE INTEGRATOR PACKAGE FOR REDUCE, VERSION 1.0
G. H. Marcel Roelofs Nov. 1992 34 p
(MEMO-1100; ETN-93-94313) Avail: CASI HC A03/MF A01

The INTEGRATOR package for REDUCE can be used to solve overdetermined systems of partial differential equations. In particular those occurring in the computation of symmetries and prolongation structures of (supersymmetric) systems of partial differential equations. The package is based on a former package developed just for the determination of symmetry groups. The reasons for the implementation of this package is the need to have one combined integrator for both cases and the availability of improved versions of some of the procedures used in former packages. Additional tools for solving more equations at a time or for solving 'exceptional' equations are provided. ESA

ALGORITHMS FOR THE MAXIMUM CLIQUE PROBLEM
J. P. vandenBerg Nov. 1992 12 p
(MEMO-1101; ETN-93-94314) Avail: CASI HC A03/MF A01

An arbitrary undirected graph G = (V,E) without multiple edges and loops is given, where V is the set of vertices and E is the set of edges. A clique is a subset of V in which all vertices are pairwise adjacent. A maximum clique is a clique with the highest cardinality in G. The algorithms presented to solve the maximum clique problem apply a branch and bound strategy. The structure of the branch and bound search tree is discussed. The branches of the branch and bound search tree which are the best to be proceeded are described. The performance of the algorithms is evaluated, using computer implementations on several random graphs with up to 3000 vertices and over one million edges. As benchmarks two algorithms are used that appeared to be the fastest algorithms known in the literature. The computational results suggest that the algorithms presented are faster than the algorithms in the literature. ESA

A FLEXIBLE MODELLING SOFTWARE FOR DATA ACQUISITION
Yantai Shu, Yanhui Chen, Songqi Yang, and Genchen Liu (Academia Sinica, Hefei, China.) Mar. 1992 15 p
(DE93-612915; CNIC-00599; ASIPP-0031) Avail: CASI HC A03/MF A01 (US Sales Only)

A flexible modeling software for data acquisition is based on an event-driven simulator. It can be used to simulate a wide variety of systems which can be modeled as open queuing networks. The main feature of the software is its flexibility to evaluate the performance of various data acquisition system, whether pulsed or not. The flexible features of this software are as follows: The user can choose the number of processors in the model and the route which every job takes to move the model. The service rate of a processor is automatically adapted. The simulator has a pipe-line mechanism. A job can be divided into several segments and a processor may be used as a compression component etc. Some modeling techniques and applications of this software in plasma physics laboratories are also presented. SUBBAND/TRANSFORM FUNCTIONS FOR IMAGE PROCESSING
Daniel Glover Jun. 1993 37 p
(RTOP 144-10-10)
(NASA-TM-106183; E-7888; NAS 1.15:106183) Avail: CASI HC A03/MF A01

Functions for image data processing written for use with the MATLAB(TM) software package are presented. These functions provide the capability to transform image data with block transformations (such as the Walsh Hadamard) and to produce spatial frequency subbands of the transformed data. Block transforms are equivalent to simple subband systems. The transform coefficients are reordered using a simple permutation to give subbands. The low frequency subband is a low resolution version of the original image, while the higher frequency subbands contain edge information. The transform functions can be cascaded to provide further decomposition into more subbands. If the cascade is applied to all four of the first stage subbands (in the case of a four band decomposition), then a uniform structure of sixteen bands is obtained. If the cascade is applied only to the low frequency subband, an octave structure of seven bands results. Functions for the inverse transforms are also given. These functions can be used for image data compression systems. The transforms do not in themselves produce data compression, but prepare the data for quantization and compression. Sample quantization functions for subbands are also given. A typical compression approach is to subband the image data, quantize it, then use statistical coding (e.g., run-length coding followed by Huffman coding) for compression. Contour plots of image data and subbanded data are shown. Author (revised)

LOW LATENCY MESSAGES ON DISTRIBUTED MEMORY MULTIPROCESSORS Final Report
Matthew Rosing and Joel Saltz (Maryland Univ., College Park.) Washington Jun. 1993 21 p Submitted for publication
(Contracts NAS1-19480; NAS1-18605; RTOP 505-90-52-01)
(NASA-CR-191479; NAS 1.26:191479; ICASE-93-30) Avail: CASI HC A03/MF A01

Many of the issues in developing an efficient interface for communication on distributed memory machines are described and a portable interface is proposed. Although the hardware component of message latency is less than one microsecond on many distributed memory machines, the software latency associated with sending and receiving typed messages is on the order of 50 microseconds. The reason for this imbalance is that the software interface does not match the hardware. By changing the interface to match the hardware more closely, applications with fine grained communication can be put on these machines. Based on several tests that were run on the iPSC/860, an interface that will better match current distributed memory machines is proposed. The model used in the proposed interface consists of a computation processor and a communication processor on each node. Communication between these processors and other nodes in the system is done through a buffered network. Information that is transmitted is either data or procedures to be executed on the remote processor. The dual processor system is better suited for efficiently handling asynchronous communications compared to a single processor system. The ability to send data or procedure is very flexible for minimizing message latency, based on the type of communication being performed. The test performed and the proposed interface are described. SYSTEM MONITORING AND DIAGNOSIS WITH QUALITATIVE MODELS Final Report, 1 Mar. 1988 - 30 Sep. 1991
Benjamin Kuipers 30 Sep. 1991 17 p
(Grant NAG2-507)
(NASA-CR-193812; NAS 1.26:193812) Avail: CASI HC A03/MF A01

A substantial foundation of tools for model-based reasoning with incomplete knowledge was developed: QSIM (a qualitative simulation program) and its extensions for qualitative simulation; Q2, Q3 and their successors for quantitative reasoning on a qualitative framework; and the CC (component-connection) and QPC (Qualitative Process Theory) model compilers for building QSIM QDE (qualitative differential equation) models starting from different ontological assumptions. Other model-compilers for QDE's, e.g., using bond graphs or compartmental models, have been developed elsewhere. These model-building tools will support automatic construction of qualitative models from physical specifications, and further research into selection of appropriate modeling viewpoints. For monitoring and diagnosis, plausible hypotheses are unified against observations to strengthen or refute the predicted behaviors. In MIMIC (Model Integration via Mesh Interpolation Coefficients), multiple hypothesized models of the system are tracked in parallel in order to reduce the 'missing model' problem. Each model begins as a qualitative model, and is unified with a priori quantitative knowledge and with the stream of incoming observational data. When the model/data unification yields a contradiction, the model is refuted. When there is no contradiction, the predictions of the model are progressively strengthened, for use in procedure planning and differential diagnosis. Only under a qualitative level of description can a finite set of models guarantee the complete coverage necessary for this performance. The results of this research are presented in several publications. Abstracts of these published papers are presented along with abtracts of papers representing work that was synergistic with the NASA grant but funded otherwise. These 28 papers include but are not limited to: 'Combined qualitative and numerical simulation with Q3'; 'Comparative analysis and qualitative integral representations'; 'Model-based monitoring of dynamic systems'; 'Numerical behavior envelopes for qualitative models'; 'Higher-order derivative constraints in qualitative simulation'; and 'Non-intersection of trajectories in qualitative phase space: a global constraint for qualitative simulation.' WAIT-FREE LINEARIZATION WITH AN ASSERTIONAL PROOF
Wim H. Hesselink Dec. 1992 31 p
(CS-9208; WHH-139-0; ETN-93-94346) Copyright Avail: CASI HC A03/MF A01

A wait-free implementation of an arbitrary data object that requires memory of order n(exp 2) and that has a time complexity of order n is presented. Given a sequential implementation of an arbitrary data object, a wait-free, linearizable concurrent implementation is constructed with space complexity quadratic in the number of processes. The worst case time complexity is linear in the number of processes. The construction is based on a compare and swap register. The programming notations, the granularity of the commands, the data objects, and concurrent linearizable implementations of data objects are explained. An easier algorithm that uses an atomic action with a larger grain of atomicity than compare and swap registers is given. The actions on the main shared variables are shown, and the linearizability under assumption of seven invariants is demonstrated. The abstract algorithm is extended with private computations and with communication by means of other shared variables. The correctness of the program is proven by means of invariants and stability properties. ESA

AN INVESTIGATION OF ERROR CHARACTERISTICS AND CODING PERFORMANCE Annual Report, Jan. - Aug. 1993
William J. Ebel and Frank M. Ingels Aug. 1993 122 p
(Grant NAG5-2006)
(NASA-CR-193620; NAS 1.26:193620) Avail: CASI HC A06/MF A02

The first year's effort on NASA Grant NAG5-2006 was an investigation to characterize typical errors resulting from the EOS dorn link. The analysis methods developed for this effort were used on test data from a March 1992 White Sands Terminal Test. The effectiveness of a concatenated coding scheme of a Reed Solomon outer code and a convolutional inner code versus a Reed Solomon only code scheme has been investigated as well as the effectiveness of a Periodic Convolutional Interleaver in dispersing errors of certain types. The work effort consisted of development of software that allows simulation studies with the appropriate coding schemes plus either simulated data with errors or actual data with errors. The software program is entitled Communication Link Error Analysis (CLEAN) and models downlink errors, forward error correcting schemes, and interleavers. Derived from text

EFFICIENT PARTITIONING AND ASSIGNMENT ON PROGRAMS FOR MULTIPROCESSOR EXECUTION Final Technical Report, 8 Feb. 1989 - 1 Oct. 1992
Hilda M. Standley 12 Jul. 1993 189 p
(Grant NAG3-975)
(NASA-CR-193458; NAS 1.26:193458) Avail: CASI HC A09/MF A02

The general problem studied is that of segmenting or partitioning programs for distribution across a multiprocessor system. Efficient partitioning and the assignment of program elements are of great importance since the time consumed in this overhead activity may easily dominate the computation, effectively eliminating any gains made by the use of the parallelism. In this study, the partitioning of sequentially structured programs (written in FORTRAN) is evaluated. Heuristics, developed for similar applications are examined. Finally, a model for queueing networks with finite queues is developed which may be used to analyze multiprocessor system architectures with a shared memory approach to the problem of partitioning. The properties of sequentially written programs form obstacles to large scale (at the procedure or subroutine level) parallelization. Data dependencies of even the minutest nature, reflecting the sequential development of the program, severely limit parallelism. The design of heuristic algorithms is tied to the experience gained in the parallel splitting. Parallelism obtained through the physical separation of data has seen some success, especially at the data element level. Data parallelism on a grander scale requires models that accurately reflect the effects of blocking caused by finite queues. A model for the approximation of the performance of finite queueing networks is developed. This model makes use of the decomposition approach combined with the efficiency of product form solutions. THE 1987 RIACS ANNUAL REPORT
20 Jun. 1987 70 p
(Contract NCC2-387)
(NASA-CR-193220; NAS 1.26:193220) Avail: CASI HC A04/MF A01

The Research Institute for Advanced Computer Science (RIACS) was established at the NASA Ames Research Center in June of 1983. RIACS is privately operated by the Universities Space Research Association (USRA), a consortium of 64 universities with graduate programs in the aerospace sciences, under several Cooperative Agreements with NASA. RIACS's goal is to provide preeminent leadership in basic and applied computer science research as partners in support of NASA's goals and missions. In pursuit of this goal, RIACS contributes to several of the grand challenges in science and engineering facing NASA: flying an airplane inside a computer; determining the chemical properties of materials under hostile conditions in the atmospheres of earth and the planets; sending intelligent machines on unmanned space missions; creating a one-world network that makes all scientific resources, including those in space, accessible to all the world's scientists; providing intelligent computational support to all stages of the process of scientific investigation from problem formulation to results dissemination; and developing accurate global models for climatic behavior throughout the world. In working with these challenges, we seek novel architectures, and novel ways to use them, that exploit the potential of parallel and distributed computation and make possible new functions that are beyond the current reach of computing machines. The investigation includes pattern computers as well as the more familiar numeric and symbolic computers, and it includes networked systems of resources distributed around the world. We believe that successful computer science research is interdisciplinary: it is driven by (and drives) important problems in other disciplines. We believe that research should be guided by a clear long-term vision with planned milestones. And we believe that our environment must foster and exploit innovation. Our activities and accomplishments for the calendar year 1987 and our plans for 1988 are reported. Author (revised)

SRI International (SRI) has carried out a three-year project to develop spoken-language understanding technology for interactive problem solving. The technology should have the following features: real-time performance, large vocabulary, high semantic accuracy, habitability, and robustness. This technology has been developed using an Air Travel Information System (ATIS) as a prototype application. We have developed technology that enables a user to retrieve airline schedules, fares, and related information by means of spoken natural-language queries. We have evaluated this technology in four ATIS benchmark evaluations, and we have incorporated it into a demonstration system, which we have also used for data collection. This final report consists of a summary of the research and other activities carried out under the project, followed by an Appendix containing 26 technical papers describing work performed on the project. The report covers work on speech recognition, natural-language understanding, speech and natural-language integration, data collection and analysis, performance evaluation, demonstration systems, and related activities. Sandia National Laboratories is prototyping a service for providing a distributed visualization capability between its Albuquerque, New Mexico and Livermore, California sites. The service will allow TCP/EP LAN users to process computationally intensive codes on the Cray Y-MP 8/864 and use the Application Visualization System, (AVS) running on a visualization server to display the results to desktops in Livermore (or Albuquerque). The long-haul environment presents several technical challenges such as high delays (up to 42 milliseconds), potential error rates, and security concerns which can affect the quality of the services. The network design requires low latency switch gear and high speed LAN connections (FDDI) to make the visualization/computational services useful to the customer. This paper will describe the network design used and will report performance characteristics of the applications utilizing this service. DOE

(DE93-011885; UCRL-JC-113502; CONF-9304114-1) Avail: CASI HC A03/MF A01

We describe C++ classes that simplify development of Adaptive Mesh Refinement (AMR) algorithms. The classes divide into two groups, generic classes that are broadly useful in adaptive algorithms, and application-specific classes that are the basis for our AMR algorithm. We employ two languages, with C++ responsible for the high-level data structures, and FORTRAN responsible for low-level numerics. The C++ implementation is as fast as the original FORTRAN implementation. Use of inheritance has allowed us to extend the original AMR algorithm to other problems with greatly reduced development time. DOE

USER'S MANUAL FOR THE DAD-1 DATA ACQUISITION DAUGHTER BOARD FOR THE SUPERCARD-2
J. R. Ferron May 1993 45 p
(Contract DE-AC03-89ER-51114)
(DE93-012153; GA-A-21236) Avail: CASI HC A03/MF A01

A detailed description of how to use the DAD-1 data acquisition daughter board is given. The DAD-1 daughter board is used with the SuperCard-2, a VME format processor board manufactured by CSP Inc. that is based on the Intel i860 microprocessor. The daughter board provides high speed acquisition of digital data through a general purpose input port. Data are transferred through direct memory access operations to the memory on the SuperCard-2 board at a rate up to 40 million, 14 bit samples per second. A first-in, first-out memory is used to buffer the data during the transfer. Several different data acquisition operating modes are available that make a combination of a SuperCard-2 processor board and a DAD-1 daughter board suitable for a wide range of real time data analysis and feedback control functions. This work presents a computer animation application, its problems and necessities of the use of dynamics principles for motion simulation. One of the major problems in computer animation is the creation of a motion that appears as natural and realistic as possible. One solution is the use of dynamics for the motion control, in which the objects are treated as having mass and other physical properties, acting under the influence of external and internal forces and torques. One difficulty with this technique is to find the forces and torques required for each motion, thus it is necessary to apply the physical laws for the motion in question. Author (revised)

A SURROGATE HEURISTIC FOR SET COVERING PROBLEMS
Luiz Antonio N. Lorena and Fabio Belo Lopes 1993 34 p Presented at Euro 12 TIMS 31 Joint International Conference, Helsinki, Finland, 29 Jun.-1 Jul. 1992
(INPE-5462-PRE/1770) Avail: CASI HC A03/MF A01

This paper presents a new heuristic for set covering problems, based upon continuous surrogate relaxation and subgradient optimization. We propose an adequate step size control that provides the surrogate bounds in few subgradient iterations, comparing to other relaxations. The algorithm also combines problem reduction tests and a technique to avoid the preliminary sorting to solve the continuous surrogate relaxation. Another feature is the definition of an efficient data structure in order to solve large set covering problems (up to 1,000 rows and 12,000 columns). Computational tests indicate better-quality results then algorithms based on Lagrangian relaxation in terms of final solutions and mainly in computer times. Author (revised)

A TOOL FOR GENERATION OF EXPERT SYSTEM SHELLS M.S. Thesis [UMA FERRAMENTA PARA A GERACAO DE ARCABOUCOS DE SISTEMAS ESPECIALISTAS]
Mauricio Marengoni Dec. 1992 95 p In PORTUGESE
(INPE-5493-TDI/510) Avail: CASI HC A05/MF A01

A tool is proposed that integrates a modular graphical interface with an expert system shell generator. The use of the tool is divided in three phases. Initially, the user interactively specifies his needs according to the intended problem. In the second phase, these specifications are used by a shell generator system to select, from a program library, the modules containing the functions needed to build an expert system shell satisfying the specifications. These modules are integrated in a stand alone system, and this system is compiled. Finally, the compiled version of the specified shell is used to develop an expert system to solve the intended problem. The tool also provides graphical primitives and mechanisms for the integration of external algorithms needed for special image manipulations. The tool implementation has been motivated by the need to construct expert systems with different levels of complexity in the domain of image processing. A further motivation was the possibility of using such a tool as a teaching and research laboratory in knowledge representation and expert system architecture. This tool represents the artificial intelligence part of a larger project of developing an intelligent laboratory for image processing, where research and product development activities could be performed efficiently. The main contribution of this work is the specification and implementation of the inference engine generator module. This module is described in details and basic theoretical aspects about the components of the module are provided. Author (revised)

THE SOLVING OF EQUATIONS BY THE METHOD OF BOUNDARY ELEMENTS [ROZWIAZYWANIE ROWNAN METODY ELEMENTOW BRZEGOWYCH]

Jacek F. Maczynski 1991 40 p In POLISH
Avail: CASI HC A03/MF A01

PASCAL procedures related to algorithms for solving systems of linear algebraic equations which arise when implementing, among others, the Boundary Element Method are presented. By Higher Algebra the matrix of the linear system may be conceived to belong to a ring upon a ring of square real matrices. The PASCAL procedures perform the operations in such a ring together with other auxiliary operations related to factorization which is known to economize memory when creating a form which is close to an inverse in a formally operational sense. These procedures (19 in number) were tested with positive results. Author (revised)

A FORMALLY VERIFIED ALGORITHM FOR INTERACTIVE CONSISTENCY UNDER A HYBRID FAULT MODEL Final Report

Patrick Lincoln and John Rushby Washington Jul. 1993 72 p
(Contract NAS1-18969; RTOP 505-64-10-13)
(NASA-CR-4527; NAS 1.26:4527) Avail: CASI HC A04/MF A01

Consistent distribution of single-source data to replicated computing channels is a fundamental problem in fault-tolerant system design. The 'Oral Messages' (OM) algorithm solves this problem of Interactive Consistency (Byzantine Agreement) assuming that all faults are worst-cass. Thambidurai and Park introduced a 'hybrid' fault model that distinguished three fault modes: asymmetric (Byzantine), symmetric, and benign; they also exhibited, along with an informal 'proof of correctness', a modified version of OM. Unfortunately, their algorithm is flawed. The discipline of mechanically checked formal verification eventually enabled us to develop a correct algorithm for Interactive Consistency under the hybrid fault model. This algorithm withstands \$a\$ asymmetric, \$s\$ symmetric, and \$b\$ benign faults simultaneously, using \$m+1\$ rounds, provided \$n is greater than 2a + 2s + b + m\$, and \$mgeg a\$. We present this algorithm, discuss its subtle points, and describe its formal specification and verification in PVS. We argue that formal verification systems such as PVS are now sufficiently effective that their application to fault-tolerance algorithms should be considered routine. Author (revised)

FLEXIBLE LANGUAGE CONSTRUCTS FOR LARGE PARALLEL PROGRAMS Final Report

Matthew Rosing and Robert Schnabel (Colorado Univ., Boulder.) Washington Jun. 1993 27 p Submitted for publication
(Contracts NAS1-18605; NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191478; NAS 1.26:191478; ICASE-93-29) Avail: CASI HC A03/MF A01

The goal of the research described is to develop flexible language constructs for writing large data parallel numerical programs for distributed memory (MIMD) multiprocessors. Previously, several models have been developed to support synchronization and communication. Models for global synchronization include SIMD (Single Instruction Multiple Data), SPMD (Single Program Multiple Data), and sequential programs annotated with data distribution statements. The two primary models for communication include implicit communication based on shared memory and explicit communication based on messages. None of these models by themselves seem sufficient to permit the natural and efficient expression of the variety of algorithms that occur in large scientific computations. An overview of a new language that combines many of these programming models in a clean manner is given. This is done in a modular fashion such that different models can be combined to support large programs. Within a module, the selection of a model depends on the algorithm and its efficiency requirements. An overview of the language and discussion of some of the critical implementation details is given. NECESSARY CONDITIONS FOR THE OPTIMALITY OF VARIABLE RATE RESIDUAL VECTOR QUANTIZERS

Faouzi Kossentini, Mark J. T. Smith, and Christopher F. Barnes 15 Jun. 1993 38 p
(Grants NAG5-2187; NSF MIP-91-16113)
(NASA-CR-193730; NAS 1.26:193730) Avail: CASI HC A03/MF A01

Residual vector quantization (RVQ), or multistage VQ, as it is also called, has recently been shown to be a competitive technique for data compression. The competitive performance of RVQ reported in results from the joint optimization of variable rate encoding and RVQ direct-sum code books. In this paper, necessary conditions for the optimality of variable rate RVQ's are derived, and an iterative descent algorithm based on a Lagrangian formulation is introduced for designing RVQ's having minimum average distortion subject to an entropy constraint. Simulation results for these entropy-constrained RVQ's (EC-RVQ's) are presented for memory less Gaussian, Laplacian, and uniform sources. A Gauss-Markov source is also considered. The performance is superior to that of entropy-constrained scalar quantizers (EC-SQ's) and practical entropy-constrained vector quantizers (EC-VQ's), and is competitive with that of some of the best source coding techniques that have appeared in the literature. EFFECTIVE SOFTWARE REUSE IN AN EMBEDDED REALTIME SYSTEM Professional Paper

B. Barlin and J. M. Lawler (Mitre Corp., San Diego, CA.) Feb. 1993 9 p
(AD-A264993) Avail: CASI HC A02/MF A01

The Submarine Message Buffer (SMB) is a real time embedded message processing system developed at the Naval Command, Control and Ocean Surveillance Center, Research, Development, Test and Evaluation Division (NRaD). The SMB is sponsored by the Space and Naval Warfare Systems Command (SPAWAR) to support modernization of SSN (Los Angeles and Seawolf class submarines) radio rooms. The development strategy adopted for the SMB concentrated on the reuse of Ada software. This paper will focus on the design, processes and methodologies, which were used in the development of this system. Metrics will also be provided showing why this system has been identified as an Ada success story by the Ada Joint Program Office among others. DTIC

AN IMPROVED MATERIAL INTERFACE RECONSTRUCTION ALGORITHM FOR EULERIAN CODES

R. L. Bell (Amparo Corp., Albuquerque, NM.) and E. S. Hertel 1992 17 p Presented at the 1992 Nuclear Explosives Code Developers Conference, Sunnyvale, CA, 2-6 Nov. 1992
(Contract DE-AC04-76DP-00789)
(DE93-011679; SAND-92-1716C; CONF-9211128-7) Avail: CASI HC A03/MF A01 (US Sales Only)

In general, shock wave physics codes can be divided into two major categories: (1) Lagrangian codes and (2) Eulerian codes. (A third category, Arbitrary Lagrangian Eulerian (ALE) codes, allows the computational mesh to move with the material until some measure of mesh distortion is achieved, then the mesh is redefined and the materials are allowed to flow through the mesh, as in an Eulerian calculation.) With Lagrangian codes the cell boundaries also form the interface between different materials in a calculation. In an Eulerian calculation, the cell boundaries may initially form the interface between materials, but as the calculation proceeds and materials flow through the mesh, material interfaces will not lie on cell boundaries. Knowledge about the location of materials in a mixed material cell is necessary to determine the correct advection of materials from a mixed cell as an Eulerian (or ALE) code calculation progresses through time. Using a material interface reconstruction algorithm that is unable to accurately determine material interface locations is analogous to running a one material problem using a first order accurate differencing scheme. The material interface reconstruction method described here is an extension to the method developed by D.L. Youngs. Youngs' method uses volume fraction information from the donor cell and all surrounding cells to determine the orientation and location of planes dividing materials from one another in a mixed material cell. Many codes use the popular Simple Line. DOE

A DISTRIBUTED VERSION OF THE NASA ENGINE PERFORMANCE PROGRAM
Jeffrey T. Cours and Brian P. Curlett Jul. 1993 9 p
(RTOP 505-69-50)
(NASA-TM-106208; E-7918; NAS 1.15:106208) Avail: CASI HC A02/MF A01

Distributed NEPP, a version of the NASA Engine Performance Program, uses the original NEPP code but executes it in a distributed computer environment. Multiple workstations connected by a network increase the program's speed and, more importantly, the complexity of the cases it can handle in a reasonable time. Distributed NEPP uses the public domain software package, called Parallel Virtual Machine, allowing it to execute on clusters of machines containing many different architectures. It includes the capability to link with other computers, allowing them to process NEPP jobs in parallel. This paper discusses the design issues and granularity considerations that entered into programming Distributed NEPP and presents the results of timing runs. Author (revised)

The Application Portable Parallel Library (APPL) is a subroutine-based library of communication primitives that is callable from applications written in FORTRAN or C. APPL provides a consistent programmer interface to a variety of distributed and shared-memory multiprocessor MIMD machines. The objective of APPL is to minimize the effort required to move parallel applications from one machine to another, or to a network of homogeneous machines. APPL encompasses many of the message-passing primitives that are currently available on commercial multiprocessor systems. This paper describes APPL (version 2.3.1) and its usage, reports the status of the APPL project, and indicates possible directions for the future. Several applications using APPL are discussed, as well as performance and overhead results. Author (revised)

A SUMMARY OF IMAGE SEGMENTATION TECHNIQUES
Lilly Spirkovska Jun. 1993 14 p
(RTOP 506-59-31)
(NASA-TM-104022; A-93082; NAS 1.15:104022) Avail: CASI HC A03/MF A01

Machine vision systems are often considered to be composed of two subsystems: low-level vision and high-level vision. Low level vision consists primarily of image processing operations performed on the input image to produce another image with more favorable characteristics. These operations may yield images with reduced noise or cause certain features of the image to be emphasized (such as edges). High-level vision includes object recognition and, at the highest level, scene interpretation. The bridge between these two subsystems is the segmentation system. Through segmentation, the enhanced input image is mapped into a description involving regions with common features which can be used by the higher level vision tasks. There is no theory on image segmentation. Instead, image segmentation techniques are basically ad hoc and differ mostly in the way they emphasize one or more of the desired properties of an ideal segmenter and in the way they balance and compromise one desired property against another. These techniques can be categorized in a number of different groups including local vs. global, parallel vs. sequential, contextual vs. noncontextual, interactive vs. automatic. In this paper, we categorize the schemes into three main groups: pixel-based, edge-based, and region-based. Pixel-based segmentation schemes classify pixels based solely on their gray levels. Edge-based schemes first detect local discontinuities (edges) and then use that information to separate the image into regions. Finally, region-based schemes start with a seed pixel (or group of pixels) and then grow or split the seed until the original image is composed of only homogeneous regions. Because there are a number of survey papers available, we will not discuss all segmentation schemes. Rather than a survey, we take the approach of a detailed overview. We focus only on the more common approaches in order to give the reader a flavor for the variety of techniques available yet present enough details to facilitate implementation and experimentation. COMPUTATIONAL MECHANICS NEEDS STUDY Final Report
O. Hayden Griffin, Jr. Aug. 1993 9 p
(Grant NAG1-675)
(NASA-CR-193712; NAS 1.26:193712) Avail: CASI HC A02/MF A01

In order to assess the needs in computational mechanics over the next decade, we formulated a questionnaire and contacted computational mechanics researchers and users in industry, government, and academia. As expected, we found a wide variety of computational mechanics usage and research. This report outlines the activity discussed with those contacts, as well as that in our own organizations. It should be noted that most of the contacts were made before the recent decline of the defense industry. Therefore, areas which are strongly defense-oriented may decrease in relative importance. In order to facilitate updating of this study, names of a few key researchers in each area are included as starting points for future literature surveys. These lists of names are not intended to represent those persons doing the best research in that area, nor are they intended to be comprehensive. They are, as previously stated, offered as starting points for future literature searches. Overall, there is currently a broad activity in computational mechanics in this country, with the breadth and depth increasing as more sophisticated software and faster computers become more available. The needs and desires of the workers in this field are as diverse as their background and organizational products. There seems to be some degree of software development in any organization (although the level of activity is highly variable from one organization to another) which has any research component in its mission. It seems, however, that there is considerable use of commercial software in almost all organizations. In most industrial research organizations, it appears that very little actual software development is contracted out, but that most is done in-house, using a mixture of funding sources. Government agencies vary widely in the ratio of in-house to out-house ratio. There is a considerable amount of experimental verification in most, but not all, organizations. Generally, the amount of experimental verification is more than we expected. Of all the survey contacts, one or two believe that the resources they are allocated are sufficient, but most do not. Some believe they have only half the resources they need. Some see their resource deficits as short-term, while others see it as a trend which will continue or perhaps worsen. The pessimism is stronger in the defense and aerospace industry. When considering only the nonlinear development efforts, there appears to be an even mix of geometric and material nonlinearity. There is not much particular emphasis in linear analysis unless it is in extension of current analysis capabilities to larger problems. The primary exception is concern about modeling of composites, where proven methodologies have trailed element and computer hardware development. Most of the people we spoke to use finite element techniques, but there is some finite difference and boundary element work ongoing. There is also some interest in multiple methods. Coupling of finite elements and boundary elements appears to be of high interest, since the two analysis types are complementary.

SCALABLE CONCURRENT PROGRAMMING PROJECT Progress Report, 27 Apr. 1992 - 22 Mar. 1993

Stephen Taylor 22 Mar. 1993 80 p
(AD-A266097) Avail: CASI HC A05/MF A01

The Scalable Concurrent Programming Project is intended to provide significant advances in scalable, high-performance, concurrent programming technology. This is to be achieved through innovations in compiler technology and programming methods. The research builds on past successes in compiler design, program development tools, programming methods and applications expertise. Two exciting directions provide the central focus for future research: fine-grain multicomputing and irregular applications. A fine-grain multicomputer is an architecture that reduces the granularity of concurrent computation by integrating hardware support for processes and messages. DTIC

GRAFTED (GRAPHICAL FAULT TREE EDITOR): A FAULT TREE DESCRIPTION PROGRAM FOR TARGET VULNERABILITY/SURVIVABILITY ANALYSIS

Frank J. Tkalcevic and Norbert M. Burman Nov. 1992 63 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A264078; MRL-GD-0043; DODA-AR-006-911) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A computer program GRAFTED, 'GRAphical Fault Tree EDitor', has been written to simplify data entry and modification of component fault tree descriptions (FTD) used in military platform vulnerability/survivability analysis procedures. GRAFTED utilizes a unique, graphical, screen based data entry procedure to define and display both individual system component parameters and their hierarchical relationship in the overall system FTD. The generated component and system FTD output is in a format which is directly readable by the MRL version of the General Vulnerability Assessment Model (GVAM), computer programs. Although GRAFTED was specifically designed to generate FTD's for GVAM, it could be easily modified to accommodate data input formats and FTD output for assessment procedures which require user friendly data entry and graphical fault tree editing and visualisation. EXPERIMENTAL SOFTWARE ENGINEERING: SEVENTEEN YEARS OF LESSONS IN THE SEL

Frank E. McGarry *In its* Proceedings of the Seventeenth Annual Software Engineering Workshop Dec. 1992 14 p (For primary document see N94-11422 01-61)
Avail: CASI HC A03/MF A04

Seven key principles developed by the Software Engineering Laboratory (SEL) at the Goddard Space Flight Center (GSFC) of the National Aeronautics and Space Administration (NASA) are described. For the past 17 years, the SEL has been experimentally analyzing the development of production software as varying techniques and methodologies are applied in this one environment. The SEL has collected, archived, and studied detailed measures from more than 100 flight dynamics projects, thereby gaining significant insight into the effectiveness of numerous software techniques, as well as extensive experience in the overall effectiveness of 'Experimental Software Engineering'. This experience has helped formulate follow-on studies in the SEL, and it has helped other software organizations better understand just what can be accomplished and what cannot be accomplished through experimentation. The concepts of quality improvements have permeated many businesses. It is clear that the nineties will be the quality era for software and there is a growing need to develop or adapt quality improvement approaches to the software business. Thus we must understand software as an artifact and software as a business. Since the business we are dealing with is software, we must understand the nature of software and software development. The software discipline is evolutionary and experimental; it is a laboratory science. Software is development not production. The technologies of the discipline are human based. There is a lack of models that allow us to reason about the process and the product. All software is not the same; process is a variable, goals are variable, etc. Packaged, reusable, experiences require additional resources in the form of organization, processes, people, etc. There have been a variety of organizational frameworks proposed to improve quality for various businesses. The ones discussed in this presentation include: Plan-Do-Check-Act, a quality improvement process based upon a feedback cycle for optimizing a single process model/production line; the Experience Factory/Quality Improvement Paradigm, continuous improvements through the experimentation, packaging, and reuse of experiences based upon a business's needs; Total Quality Management, a management approach to long term success through customer satisfaction based on the participation of all members of an organization; the SEI capability maturity model, a staged process improvement based upon assessment with regard to a set of key process areas until you reach a level 5 which represents a continuous process improvement; and Lean (software) Development, a principle supporting the concentration of the production on 'value added' activities and the elimination of reduction of 'not value added' activities. THE MERMAID PROJECT

A. J. C. Cowderoy, John O. Jenkins, and A Poulymenakou *In* NASA. Goddard Space Flight Center, Proceedings of the Seventeenth Annual Software Engineering Workshop Dec. 1992 19 p (For primary document see N94-11422 01-61)

Avail: CASI HC A03/MF A04

The tendency for software development projects to be completed over schedule and over budget was documented extensively. Additionally many projects are completed within budgetary and schedule target only as a result of the customer agreeing to accept reduced functionality. In his classic book, The Mythical Man Month, Fred Brooks exposes the fallacy that effort and schedule are freely interchangeable. All current cost models are produced on the assumption that there is very limited scope for schedule compression unless there is a corresponding reduction in delivered functionality. The Metrication and Resources Modeling Aid (MERMAID) project, partially financed by the Commission of the European Communities (CEC) as Project 2046 began in Oct. 1988 and its goal were as follows: (1) improvement of understanding of the relationships between software development productivity and product and process metrics; (2) to facilitate the widespread technology transfer from the Consortium to the European Software Industry; and (3) to facilitate the widespread uptake of cost estimation techniques by the provision of prototype cost estimation tools. MERMAID developed a family of methods for cost estimation, many of which have had tools implemented in prototypes. These prototypes are best considered as toolkits or workbenches. Author (revised)

THE ROLE OF METRICS AND MEASUREMENTS IN A SOFTWARE INTENSIVE TOTAL QUALITY MANAGEMENT ENVIRONMENT

Charles B. Daniels *In* NASA. Goddard Space Flight Center, Proceedings of the Seventeenth Annual Software Engineering Workshop Dec. 1992 29 p (For primary document see N94-11422 01-61)

Avail: CASI HC A03/MF A04

Paramax Space Systems began its mission as a member of the Rockwell Space Operations Company (RSOC) team which was the successful bidder on a massive operations consolidation contract for the Mission Operations Directorate (MOD) at JSC. The contract awarded to the team was the Space Transportation System Operations Contract (STSOC). Our initial challenge was to accept responsibility for a very large, highly complex and fragmented collection of software from eleven different contractors and transform it into a coherent, operational baseline. Concurrently, we had to integrate a diverse group of people from eleven different companies into a single, cohesive team. Paramax executives recognized the absolute necessity to develop a business culture based on the concept of employee involvement to execute and improve the complex process of our new environment. Our executives clearly understood that management needed to set the example and lead the way to quality improvement. The total quality management policy and the metrics used in this endeavor are presented. Derived from text

REUSE: A KNOWLEDGE-BASED APPROACH

Neil Iscoe, Zheng-Yang Liu, and Guohui Feng *In* NASA. Goddard Space Flight Center, Proceedings of the Seventeenth Annual Software Engineering Workshop Dec. 1992 23 p (For primary document see N94-11422 01-61)

Avail: CASI HC A03/MF A04

This paper describes our research in automating the reuse process through the use of application domain models. Application domain models are explicit formal representations of the application knowledge necessary to understand, specify, and generate application programs. Furthermore, they provide a unified repository for the operational structure, rules, policies, and constraints of a specific application area. In our approach, domain models are expressed in terms of a transaction-based meta-modeling language. This paper has described in detail the creation and maintenance of hierarchical structures. These structures are created through a process that includes reverse engineering of data models with supplementary enhancement from application experts. Source code is also reverse engineered but is not a major source of domain model instantiation at this time. In the second phase of the software synthesis process, program specifications are interactively synthesized from an instantiated domain model. These specifications are currently integrated into a manual programming process but will eventually be used to derive executable code with mechanically assisted transformations. This research is performed within the context of programming-in-the-large types of systems. Although our goals are ambitious, we are implementing the synthesis system in an incremental manner through which we can realize tangible results. The client/server architecture is capable of supporting 16 simultaneous X/Motif users and tens of thousands of attributes and classes. Domain models have been partially synthesized from five different application areas. As additional domain models are synthesized and additional knowledge is gathered, we will inevitably add to and modify our representation. However, our current experience indicates that it will scale and expand to meet our modeling needs. Author

LARGE PROJECT EXPERIENCES WITH OBJECT-ORIENTED METHODS AND REUSE

William Wessale (CAE Industries Ltd., Montreal, Quebec.), Donald J. Reifer (Reifer Consultants, Inc., Torrance, CA.), and David Weller (CAE Industries Ltd., Montreal, Quebec.) *In its* Proceedings of the Seventeenth Annual

Software Engineering Workshop Dec. 1992 22 p (For primary document see N94-11422 01-61)
Avail: CASI HC A03/MF A04

The SSVTF (Space Station Verification and Training Facility) project is completing the Preliminary Design Review of a large software development using object-oriented methods and systematic reuse. An incremental developmental lifecycle was tailored to provide early feedback and guidance on methods and products, with repeated attention to reuse. Object oriented methods were formally taught and supported by realistic examples. Reuse was readily accepted and planned by the developers. Schedule and budget issues were handled by agreements and work sharing arranged by the developers. Author

DEVELOPMENT AND APPLICATION OF AN ACCEPTANCE TESTING MODEL
Rex D. Pendley, Caroline H. Noonan, and Kenneth R. Hall *In* NASA. Goddard Space Flight Center, Proceedings of the Seventeenth Annual Software Engineering Workshop Dec. 1992 27 p (For primary document see N94-11422 01-61)
Avail: CASI HC A03/MF A04

The process of acceptance testing large software systems for NASA has been analyzed, and an empirical planning model of the process constructed. This model gives managers accurate predictions of the staffing needed, the productivity of a test team, and the rate at which the system will pass. Applying the model to a new system shows a high level of agreement between the model and actual performance. The model also gives managers an objective measure of process improvement. Author

A RECENT CLEANROOM SUCCESS STORY: THE REDWING PROJECT
c14
Philip A. Hausler *In* NASA. Goddard Space Flight Center, Proceedings of the Seventeenth Annual Software Engineering Workshop Dec. 1992 30 p (For primary document see N94-11422 01-61)
Avail: CASI HC A03/MF A04

Redwing is the largest completed Cleanroom software engineering project in IBM, both in terms of lines of code and project staffing. The product provides a decision-support facility that utilizes artificial intelligence (AI) technology for predicting and preventing complex operating problems in an MVS environment. The project used the Cleanroom process for development and realized a defect rate of 2.6 errors/KLOC, measured from first execution. This represents the total amount of errors that were found in testing and installation at three field test sites. Development productivity was 486 LOC/PM, which included all development labor expended in design specification through completion of incremental testing. In short, the Redwing team produced a complex systems software product with an extraordinarily low error rate, while maintaining high productivity. All of this was accomplished by a project team using Cleanroom for the first time. An 'introductory implementation' of Cleanroom was defined and used on Redwing. This paper describes the quality and productivity results, the Redwing project, and how Cleanroom was implemented.

INSIGHTS INTO SOFTWARE DEVELOPMENT IN JAPAN
Lorraine M. Duvall *In* NASA. Goddard Space Flight Center, Proceedings of the Seventeenth Annual Software Engineering Workshop Dec. 1992 19 p (For primary document see N94-11422 01-61)
Avail: CASI HC A03/MF A04

The interdependence of the U.S.-Japanese economies makes it imperative that we in the United States understand how business and technology developments take place in Japan. We can gain insight into these developments in software engineering by studying the context in which Japanese software is developed, the practices that are used, the problems encountered, the setting surrounding these problems, and the resolution of these problems. Context includes the technological and sociological characteristics of the software development environment, the software processes applied, personnel involved in the development process, and the corporate and social culture surrounding the development. Presented in this paper is a summary of results of a study that addresses these issues. Data for this study was collected during a three month visit to Japan where the author interviewed 20 software managers representing nine companies involved in developing software in Japan. These data are compared to similar data from the United States in which 12 managers from five companies were interviewed. Author

MYTHS AND REALITIES: DEFINING RE-ENGINEERING FOR A LARGE ORGANIZATION
Sandra Yin and Julia McCreary *In* NASA. Goddard Space Flight Center, Proceedings of the Seventeenth Annual Software Engineering Workshop Dec. 1992 40 p (For primary document see N94-11422 01-61)
Avail: CASI HC A03/MF A04

This paper describes the background and results of three studies concerning software reverse engineering, re-engineering, and reuse (R3) hosted by the Internal Revenue Service in 1991 and 1992. The situation at the Internal Revenue--aging, piecemeal computer systems and outdated technology maintained by a large staff--is familiar to many institutions, especially among management information systems. The IRS is distinctive for the sheer magnitude and diversity of its problems; the country's tax records are processed using assembly language and COBOL and spread across tape and network DBMS files. How do we proceed with replacing legacy systems? The three software re-engineering studies looked at methods, CASE tool support, and performed a prototype project using re-engineering methods and tools. During the course of these projects, we discovered critical issues broader than the mechanical definitions of methods and tool technology. Author (revised)

STGT (Second TDRSS Ground Terminal) is currently halfway through the System Integration Test phase (Level 4 Testing). To date, many software architecture and Ada language issues have been encountered and solved. This paper, which is the transcript of a presentation at the 3 Dec. meeting, attempts to define these lessons plus others learned regarding software project management and risk management issues, training, performance, reuse, and reliability. Observations are included regarding the use of particular Ada coding constructs, software architecture trade-offs during the prototyping, development and testing stages of the project, and dangers inherent in parallel or concurrent systems, software, hardware, and operations engineering. DISCRETE KALMAN FILTERING EQUATIONS OF SECOND-ORDER FORM FOR CONTROL-STRUCTURE INTERACTION SIMULATIONS

K. C. Park (Colorado Univ., Boulder.), K. F. Alvin (Colorado Univ., Boulder.), and W. Keith Belvin 1991 24 p
(Grant NAG9-574)
(NASA-CR-193723; NAS 1.26:193723; AIAA Paper 90-3387) Avail: CASI HC A03/MF A01

A second-order form of discrete Kalman filtering equations is proposed as a candidate state estimator for efficient simulations of control-structure interactions in coupled physical coordinate configurations as opposed to decoupled modal coordinates. The resulting matrix equation of the present state estimator consists of the same symmetric, sparse N x N coupled matrices of the governing structural dynamics equations as opposed to unsymmetric 2N x 2N state space-based estimators. Thus, in addition to substantial computational efficiency improvement, the present estimator can be applied to control-structure design optimization for which the physical coordinates associated with the mass, damping and stiffness matrices of the structure are needed instead of modal coordinates. BOUNDING THE VAPNIK-CHERVONENKIS DIMENSION OF CONCEPT CLASSES PARAMETERIZED BY REAL NUMBERS

P. Goldberg and M. Jerrum (Edinburgh Univ., Scotland.) 1993 11 p
Presented at the Conference on Learning Theory, Santa Cruz, CA, 26-28 Jul. 1993
(Contract DE-AC04-76DP-00789)
(DE93-011600; SAND-93-0483C; CONF-930772-1) Avail: CASI HC A03/MF A01

The Vapnik-Chervonenkis (V-C) dimension is an important combinatorial tool in the analysis of learning problems in the PAC framework. For polynomial learnability, we seek upper bounds on the V-C dimension that are polynomial in the syntactic complexity of concepts. Such upper bounds are automatic for discrete concept classes, but hitherto little has been known about what general conditions guarantee polynomial bounds on V-C dimension for classes in which concepts and examples are represented by tuples of real numbers. In this paper, we show that for two general kinds of concept class the V-C dimension is polynomially bounded as a function of the syntactic complexity of concepts. One is classes where the criterion for membership of an instance in a concept can be expressed as a formula with fixed quantification depth and exponentially-bounded length, whose atomic predicates are polynomial inequalities of exponentially-bounded degree. The other is classes where containment of an instance in a concept is testable in polynomial time, assuming we may compute standard arithmetic operations on reals exactly in constant time. Our results show that in the continuous case, as in the discrete, the real barrier to efficient learning in the Occam sense is complexity-theoretic and not information-theoretic. We present examples to show how these results apply to concept classes defined by geometrical figures and neural nets. Polynomial bounds on V-C dimension are derived for these classes, apparently for the first time. DOE

PARAMETRIC STUDY OF DIFFUSION-ENHANCEMENT NETWORKS FOR SPATIOTEMPORAL GROUPING IN REAL-TIME ARTIFICIAL VISION Final Technical Report

Robert K. Cunningham and Allen M. Waxman 6 Apr. 1993 70 p
Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F19628-90-C-0002)
(AD-A265065; ESC-TR-92-207) Avail: CASI HC A04

Spatiotemporal grouping phenomena are examined in the context of static and time-varying imagery. Dynamics that exhibit static feature grouping on multiple scales as a function of time and long-range apparent motion between time-varying inputs are developed for a biologically plausible diffusion-enhancement bilayer network. The architecture consists of a diffusion layer and a contrast-enhancement layer coupled by feedforward and feedback connections; time-varying input is provided by a separate feature extracting layer. The model is cast as an analog circuit that is realizable in very large scale integration, the parameters of which are selected to satisfy a psychophysical database of the following long-range apparent motion phenomena: gamma motion of a single light, smooth motion between two lights, reverse motion, split and merge among three lights, Ternus motion among multiple lights, and peripheral motion. The relation between motion on a uniform network (i.e, cortex) and inputs to a nonuniform sampling array (i.i, retina) are discussed in the context of a logarithmic scaling of space. A new interpretation of short- and long-range visual motion systems is introduced. DTIC

RAMCAD (RELIABILITY, AVAILABILITY, AND MAINTAINABILITY IN COMPUTER-AIDED DESIGN) Final Report, Jul. 1987 - Jul. 1991

William J. Dawson, Peter J. Glor, Mary A. Klement, James C. McManus, and Sid E. Markowitz Nov. 1992 111 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F33615-87-C-0003)
(AD-A265143; GDC-RAMCAD-91-019; AL-TR-1992-0058) Avail: CASI HC A06

The Reliability, Availability and Maintainability in Computer-Aided Design (RAMCAD) Program was established by the Air Force Armstrong Laboratory (AL/HRGA) in 1987 as a direct result of the Computer-Aided Acquisition and Logistics Support (CALS) Initiatives. The purpose of RAMCAD was to solicit new and creative solutions to the problem of integrating Reliability, Maintainability, and Supportability into Computer-Aided Design. To provide a near-term RAMCAD capability, a principle task, funded by Armstrong Laboratory and the Army Armament, Munitions, and Chemical Command (AMCCOM) was contracted to General Dynamics to integrate stand-alone commercially available or public domain reliability, maintainability, and supportability analysis software with a computer-aided design workstation for electronic, mechanical, and structural design as a RAMCAD Prototype system. RAMCAD provides a common user interface and shared database for reliability, maintainability, and supportability of electronic, mechanical, and structural designs. Execution of analysis programs is transparent to the user through the common user interface. Additionally, RAMCAD provides a significant process improvement in the quality and robustness of reliability predictions for new designs. This is accomplished by analysis of the environmental stresses experienced by each component in the system, rather than relying on default values or average values for the unit under analysis. This report documents the development of the RAMCAD Prototype System and Lessons Learned. DTIC

COMPUTATIONAL ALGORITHMS OR IDENTIFICATION OF DISTRIBUTED PARAMETER SYSTEMS Final Technical Report, 1 Sep. 1989 - 28 Feb. 1993

Dennis W. Brewer and Robert K. Powers 24 Apr. 1993 78 p
(Grant AF-AFOSR-0472-89)
(AD-A265252; AFOSR-93-0361TR) Avail: CASI HC A05/MF A01

This research established a general framework for the convergence of a parameter estimation algorithm based on quasi-linearization which applies to a class of distributed parameter systems described by linear dynamical systems. Conditions were established which guarantee local convergence of the identification algorithm. The algorithm was applied to delay and coefficient identification in systems of delay-differential equations. Such systems have been proposed as hereditary models of aeroelastic systems. A numerical identification algorithm was developed and tested for estimating parameters in a Volterra integral equation arising from a viscoelastic model of a flexible structure with Boltzmann damping. In particular, one of the parameters identified was the order of the derivative in Volterra integro-differential equations containing fractional derivatives, a form of viscoelastic damping. A Galerkin approximation in the space variable was used to approximate the partial differential equation with memory by a system of integro-differential equations. Numerical experiments were performed to test the ability of the algorithm to estimate unknown damping parameters in these systems. DTIC

COSMIC MONTHLY PROGRESS REPORT
Aug. 1993 43 p
(Contract NASw-4670)
(NASA-CR-194400; NAS 1.26:194400) Avail: CASI HC A03/MF A01

Activities of the Computer Software Management and Information Center (COSMIC) are summarized for the month of August, 1993. Tables showing the current inventory of programs available from COSMIC are presented and program processing and evaluation activities are discussed. Ten articles were prepared for publication in the NASA Tech Brief Journal. These articles (included in this report) describe the following software items: (1) MOM3D - A Method of Moments Code for Electromagnetic Scattering (UNIX Version); (2) EM-Animate - Computer Program for Displaying and Animating the Steady-State Time-Harmonic Electromagnetic Near Field and Surface-Current Solutions; (3) MOM3D - A Method of Moments Code for Electromagnetic Scattering (IBM PC Version); (4) M414 - MIL-STD-414 Variable Sampling Procedures Computer Program; (5) MEDOF - Minimum Euclidean Distance Optimal Filter; (6) CLIPS 6.0 - C Language Integrated Production System, Version 6.0 (Macintosh Version); (7) CLIPS 6.0 - C Language Integrated Production System, Version 6.0 (IBM PC Version); (8) CLIPS 6.0 - C Language Integrated Production System, Version 6.0 (UNIX Version); (9) CLIPS 6.0 - C Language Integrated Production System, Version 6.0 (DEC VAX VMS Version); and (10) TFSSRA - Thick Frequency Selective Surface with Rectangular Apertures. Activities in the areas of marketing, customer service, benefits identification, maintenance and support, and dissemination are also described along with a budget summary. CASI

ANALYSIS AND GUIDELINES FOR REUSABLE Ada SOFTWARE Final Report
David A. Wheeler Aug. 1992 53 p
(Contract MDA903-89-C-0003)
(AD-A264918; IDA-P-2765; IDA/HQ-92-042441; AD-E501655) Avail: CASI HC A04/MF A01

SDIO is developing the Global Protection Against Limited Strikes (GPALS) system. Much of the software is to be developed in Ada, and software reuse will be considered in the software design and implementation phases. This document provides an analysis and candidate guidelines for developing reusable Ada software to supplement existing SDIO guidelines. The guidelines in this document are based on previous IDA work, IDA Paper P-2378, 'An Approach for Constructing Reusable Components in Ada' by Stephen Edwards. In addition, two other sources were examined: GPALS Software Standards by GE Aerospace, and Ada Quality and Style: Guidelines for Professional Programmers by the Software Productivity Consortium. The analysis shows that many of Edwards's guidelines are already included in Ada Quality and Style and thus will already be used by SDIO. Some of the guidelines require further research before inclusion in a candidate set of guidelines. The remaining guidelines are presented as candidate guidelines in a form similar to that of Ada Quality and Style. This document presents the candidate guidelines in a form which could be readily added to existing Ada development guidelines. DTIC

N94-11860# Air Force Inst. of Tech., Wright-Patterson AFB, OH.
DEVELOPMENT AND IMPLEMENTATION OF A GENERAL PURPOSE X-WINDOWS DISPLAY PROGRAM M.S. Thesis
Gregory D. Carson Dec. 1992 98 p
(AD-A265306; AFIT/CI/CIA-92-128) Avail: CASI HC A05/MF A02

The purpose of the work presented was to design and develop a portable, easy-to-use software package capable of displaying a gray scale image. The display of an image was in actuality only a part of the work. The program was also required to be both FORTRAN and C callable. Additionally, the program had to provide the user with the capability to draw on the image in color, and import tracings, or contours, and display them on the image. The final requirement was to engage recursive use of the program, to provide the ability to display multiple images simultaneously. This work is a presentation of the program developed to meet the above stated requirements. The program is called SEP. The first chapter contains a brief discussion of the reasoning behind the choice of the windowing system utilized. Also presented is an overview of the terminology and concepts involved in using that windowing system. The second chapter describes the internal operations of the program and how it meets the requirements. The third chapter is a description of the method used to interface the developed program to other computer programs. The fourth chapter then provides an explanation of how to use the developed program. The final chapter is a discussion of the testing and evaluation done to ensure the program meets its goal. DOE

N94-11874# Naval Postgraduate School, Monterey, CA.
THE RATIONAL BEHAVIOR MODEL: A MULTI-PARADIGM, TRI-LEVEL SOFTWARE ARCHITECTURE FOR THE CONTROL OF AUTONOMOUS VEHICLES Ph.D. Thesis
Ronald B. Byrnes, Jr. Mar. 1993 317 p
(AD-A265175) Avail: CASI HC A14/MF A03

There is currently a very strong interest among researchers in the fields of artificial intelligence and robotics in finding more effective means of linking high level symbolic computations relating to mission planning and control for autonomous vehicles to low level vehicle control software. The diversity exhibited by the many processes involved in such control has resulted in a number of proposals for a general software architecture intended to provide an efficient yet flexible framework for the organization and interaction of relevant software components. The Rational Behavior Model (RBM) has been developed with these requirements in mind and consists of three levels, called the Strategic, the Tactical, and the Execution levels, respectively. Each level reflects computations supporting the solution to the global control problem based on different abstraction mechanisms. The unique contribution of the RBM architecture is the idea of specifying different programming paradigms to realize each software level. Specifically, RBM uses rule-based programming for the Strategic level, thereby permitting field reconfiguration of missions by a mission specialist without reprogramming at lower levels. The Tactical level realizes vehicle behaviors as the methods of software objects programmed in an object-based language such as Ada. These behaviors are initiated by rule satisfaction at the Strategic level, thereby rationalizing their interaction. The Execution level is programmed in any imperative language capable of supporting efficient execution of real-time control of the underlying vehicle hardware. DTIC

SYSTEM ENGINEERING CONCEPT DEMONSTRATION, PROCESS MODEL, VOLUME 3 Final Report, Feb. 1990 - Jul. 1992
Alberto Ortiz Dec. 1992 130 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F30602-90-C-0021)
(AD-A265469; RL-TR-92-345-Vol-3) Avail: CASI HC A07

This is the third volume of the Final Technical Report (FTR) for the System Engineering Concept Demonstration (SECD) which was sponsored and managed by the Air Force Rome Laboratory (RL). The SECD was an exploratory development effort which culminated in Catalyst, a fully researched and specified system concept which provides an automated environment of integrated, state-of-the-art software tools and methods. This document reports the results of the SECD Process Model Task. The SECD Process Model is a system acquisition and development model that emphasizes System Engineering activities over the entire system lifecycle. The Process model is a graphical representation of the System Engineering Lifecycle activities, agents, flows, feedbacks, and work products. This interactive Process Model provides a multi-dimensional view of government acquisition and contractor development activities. An integral part of the SECD program, the Process Model aided in developing the system's requirements which are documented in the System/Segment Specification (SSS). The model also demonstrated coverage and completeness of the System Engineering process. DTIC

THE INSTRUMENTATION OF THE MULTIMODEL AND MULTILINGUAL USER INTERFACE M.S. Thesis
Paul A. Bourgeois Mar. 1993 126 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A265444) Avail: CASI HC A07

The traditional approach to database management system (DBMS) designs focuses upon the implementation of a single data model and its corresponding data language in order to support applications for a given database task. Each of these monomodel and monolingual database systems represents a homogeneous database system, since only one data model-language can be supported on a single database system. The application diversity forces many organizations to operate several different homogeneous database systems to support its operations. A different approach to database-system design is the development of a DBMS which supports multiple data models and their data language. This approach is the focus of the multimodel and multilingual database system (MM and MLDS) as implemented on the Multibackend Database Supercomputer (MDBS). With the proliferation of new data model-languages in the database technology, the objective of MM&MLDS is to incorporate these new data model-languages onto the same MDBS. The goal is to develop procedures, methods, and tools for the incorporation of new data model-languages into MM&MLDS as new interfaces. Three areas of research are critical to achieving this goal: (1) the development of a MDBS user's manual for familiarization as well as instruction for system users; (2) the specifications of generic processing algorithms used as a foundation for each module of the new model-language interface; and (3) our software methodology considerations for new data model-language interface implementation. A NEW HEURISTIC FOR SET COVERING PROBLEMS Thesis [UMA NOVA HEURISTICA PARA PROBLEMAS DE COBERTURA DE CONJUNTOS]
Fabio Belo Lopes Oct. 1992 70 p In PORTUGESE
(INPE-5471-TDI/502) Avail: CASI HC A04/MF A01

This work presents a new heuristic for set covering problems, based upon Continuous Surrogate relaxation and subgradient optimization. We propose an adequate step size control that provides the Surrogate bounds in few subgradient iterations, compared to other relaxations. The algorithm also combines problem reduction tests and a technique to avoid the preliminary sorting to solve the Continuous Surrogate relaxation. Another feature is the definition of an efficient data structure in order to solve large set covering problems (up to 1,000 rows and 12,000 columns). Computational tests indicate better-quality results than algorithms based on Lagrangian relaxation in terms of final solutions and mainly in computer times. Author

ESA COSTING SOFTWARE (ECOS) INTRODUCTION
Stefan Heerd, ed. 1992 6 p Limited Reproducibility: More than 20% of this document may be affected by color photographs Original contains color illustrations
(ESA-F-28) Copyright Avail: CASI HC A02/MF A01

The European Space Agency and its industrial partners have considerable experience of the demands placed on the management of technically complex, multi-national projects. It is not surprising therefore that to assist management, ESA developed a procedure for determining the allocation of tasks to industry during each phase of complex, multi-contractor projects. To minimize paperwork in this procedure, the Cost Analysis Division at ESTEC introduced the ESA Costing Software, ECOS. With ECOS, work can be divided down the industrial structure, and cost proposals can be generated and passes to higher levels of management. Data can be transferred to ESA either by telecommunications link or on diskettes. CASI

AVOIDANCE AND SUPPRESSION OF COMPENSATION CODE IN A TRACE SCHEDULING COMPILER
S. M. Freudenberger, T. R. Gross, and P. G. Lowney Apr. 1993 50 p
(AD-A265612; CMU-CS-93-145) Avail: CASI HC A03/MF A01

Trace scheduling is an optimization technique that selects a sequence of basic blocks as a trace and schedules the operations from the trace. If an operation is moved across basic block boundaries, one or more compensation copies may be required in the off-trace code. This paper discusses the generation of compensation code in a trace scheduling compiler and presents techniques for limiting the amount of compensation code: avoidance (restricting code motion so that no compensation code is required) and suppression (analyzing the global flow of the program to detect when a copy is redundant). We evaluate the effectiveness of these techniques based on measurements for the SPEC89 suite and the Livermore Fortran Kernels, using our implementation of trace scheduling for a Multiflow Trace 7/300. The paper compares different compiler models, contrasting the performance of trace scheduling with the performance obtained from typical RISC compilation techniques. There are two key results of this study: First, the amount of compensation code generated is not large. For the SPEC89 suite, the average code size-increase due to trace scheduling is 6%. Avoidance is more important than suppression, although there are some kernels that benefit significantly from compensation code suppression. Since compensation code is not a major issue, a compiler can be more aggressive in code motion and loop unrolling. DTIC

Radiosity algorithms for global illumination, either 'gathering' or 'shooting' versions, depend on the calculation of form factors. It is possible to calculate the form factors analytically, but this is difficult when occlusion is involved, so sampling methods are usually preferred. The necessary visibility information can be obtained by ray tracing in the sampled directions. However, area coherence makes it more efficient to project and scan-convert the scene onto a number of planes, for example, the faces of a hemicube. The hemicube faces have traditionally been divided into equal square pixels, but more general subdivisions are practical and can reduce the variance of the form factor estimates. The hemicube estimates of form factors are based on a finite set of sample directions. We obtain several optimal arrangements of sample directions, which minimize the variance of this estimate. Four approaches are changing the size of the pixels, the shape of the pixels, the shape of the hemicube, or using non-uniform pixel grids. The best approach reduces the variance by 43%. The variance calculation is based on the assumption that the errors in the estimate are caused by the projections of single edges of polygonal patches, and that the positions and orientations of these edges are random. FINDING A COVERING TRIANGULATION WHOSE MAXIMUM ANGLE IS PROVABLY SMALL
S. A. Mitchell and J. K. Park 3 Mar. 1993 13 p Presented at the Workshop on Algorithms and Data Structures, Montreal, Canada, 11-13 Aug. 1993
(Contract DE-AC04-76DP-00789)
(DE93-010691; SAND-93-0690C; CONF-930884-2) Avail: CASI HC A03/MF A01

Given a planar straight-line graph, we find a covering triangulation whose maximum angle is as small as possible. A covering triangulation is a triangulation whose vertex set contains the input vertex set and whose edge set contains the input edge set. Such a triangulation differs from the usual Steiner triangulation in that we may not add a Steiner vertex on any input edge. Covering triangulations provide a convenient method for triangulating multiple regions sharing a common boundary, as each region can be triangulated independently. As it is possible that no finite covering triangulation is optimal in terms of its maximum angle, we propose an approximation algorithm. Our algorithm produces a covering triangulation whose maximum angle gamma is probably close to gamma(sub opt), a lower bound on the maximum angle in any covering triangulation of the input graph. Note that we must have gamma less than or equal to 3(gamma)(sub opt), since we always have gamma(sub opt) greater than or equal to pi/3 and no triangulation can contain an angle of size greater than pi. We prove something significantly stronger. We show that pi - gamma greater than or equal to (pi - gamma(sub opt))/6, i.e., our gamma is not much closer to pi than is gamma(sub opt). This result represents the first nontrivial bound on a covering triangulation's maximum angle. We require a subroutine for the following problem: given a polygon with holes, find a Steiner triangulation whose maximum angle is bounded away from pi. No angle larger than 8(pi)/9 is sufficient for the bound on gamma claimed above. The number of Steiner vertices added by our algorithm and its running time are highly dependent on the corresponding bounds for the subroutine. Given an n-vertex planar straight-line graph, we require O(n + S(n)) Steiner vertices and O(n log n + T(n)) time, where S(n) is the number of Steiner vertices added by the subroutine and T(n) is its running time for an O(n)-vertex polygon with holes. (Contract DE-AC04-76DP-00789)
(DE93-013961; SAND-93-0858) Avail: CASI HC A03/MF A01 (US Sales Only)

This report describes the models and algorithms used in the Air Force Electronic Warfare Center's (AFEWC's) Improved Many-on-Many (IMOM) ROUTE simulation software. ROUTE simulates an attack aircraft as it penetrates enemy territory that is protected by ground-based search and tracking radars and ground-to-air defensive weapon systems. Self-protection and stand-off jamming are also modelled in the simulation. The overall algorithm for computing the effectiveness of several radars on a single aircraft is described. In particular, the algorithms and mathematical models for calculating the radar range equation, terrain effects using DMA mapping information, weapon system performance, and geometry are described. In addition, the mathematical models and algorithms for calculating the degradation of early-seaming, target-acquisition, fire-control, height-finding, and target-tracking radars due to stand-off and self-protection jammers are described. This document will be useful for analysts who use IMOM and for software developers who modify and extend IMOM's capabilities. Our analysis has examined and validated the theoretical bases for the IMOM ROUTE simulation and its implementation in the software. During the analysis, questions, comments, and concerns were communicated to AFEWC. DOE

The development of highly parallel direct solvers for large, sparse linear systems of equations (e.g. for finite element or finite difference models) is lagging behind progress in parallel direct solvers for dense matrices and iterative methods for sparse matrices. We describe a massively parallel (MP) multifrontal solver for the direct solution of large sparse linear systems, such as those routinely encountered in finite element structural analysis, in an effort to address concerns about the viability of scalable, MP direct methods for sparse systems and enhance the software base for MP applications. Performance results are presented and future directions are outlined for research and development efforts in parallel multifrontal and related solvers. In particular, parallel efficiencies of 25% on 1024 NCUBE 2 nodes and 36% on 64 Intel iPSC860 nodes have been demonstrated, and parallel efficiencies of 60-85% are expected when a severe load imbalance is overcome by static mapping and dynamic load balance techniques previously developed for other parallel solvers and application codes. A language which makes clear the distinction between temporal order and causal order is presented. This allows for a transformational approach, in an algebraic way, to the specification and verification of concurrent systems. One of these is an algebraic formulation of the communication closed layers principle. These laws suffice to rewrite process terms that avoid specification of temporal ordering into a unique normal form. Other transformations allow for gradually imposing temporal ordering on an already functionally correct design. The combination of such laws enables a design strategy where architecture independent designs are transformed towards a form that matches a particular implementation architecture. This style of design is applied to various distributed algorithms, including the following: an algorithm for the 'point-in-polygon' problem transformed to a form suitable for pipeline execution on a tree network; the Floyd-Warshall algorithm for the all points shortest path transformed to a form suitable for execution on a Single Instruction Multiple Data stream (SIMD) architecture; and the CYK algorithm for parsing context free languages, on a Multiple Instruction Multiple Data stream (MIMD) architecture. Particle-tracking simulation is one of the scientific applications that is well-suited to parallel computations. At the Superconducting Super Collider, it has been theoretically and empirically demonstrated that particle tracking on a designed lattice can achieve very high parallel efficiency on a MIMD Intel iPSC/860 machine. The key to such success is the realization that the particles can be tracked independently without considering their interaction. The perfectly parallel nature of particle tracking is broken if the interaction effects between particles are included. The space charge introduces an electromagnetic force that will affect the motion of tracked particles in 3-D space. For accurate modeling of the beam dynamics with space charge effects, one needs to solve three-dimensional Maxwell field equations, usually by a particle-in-cell (PIC) algorithm. This will require each particle to communicate with its neighbor grids to compute the momentum changes at each time step. It is expected that the 3-D PIC method will degrade parallel efficiency of a particle-tracking implementation on any parallel computer. In this paper, we describe an efficient scheme for implementing particle tracking with space charge effects on an INTEL iPSC/860 machine. Experimental results show that a parallel efficiency of 75% can be obtained. DOE

Using the National Aerospace Laboratory (NAL) numerical simulater, a software program simulating a parallel computer configurated with 128 x 256 processing elements was run following the implementation of its associated assembly language. The software simulates a parallel computer's memory access and register operation at the clock level and generates an operational time diagram along with results, whereas the assembly language describe its execution procedures. The operation of this computer was evaluated by employing a basic function subroutine, with the instruction set and network between the memory and the processing elements, being subsequently examined, thereby enabling estimation of its maximum efficiency. In addition, efficiency was further evaluated by comparing the resultant parallel processing time using a two dimensional computational fluid dynamics program to the corresponding sequential processing time obtained with a processing element. BRINGING THEORY TO PRACTICE: THE REALITY OF INTERPROCESSOR COMMUNICATION

D. S. Greenberg and K. S. McCurley 1993 5 p Presented at the Workshop on Analyzing Scalibility of Parallel Algorithms, Newport Beach, CA, 13 Apr. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC04-76DP-00789)
(DE93-012346; SAND-93-0955; CONF-9304140-1) Avail: CASI HC A01

Determining the best topology for the interconnection network of a scalable processor is not possible via theoretical models. However, we might hope that theoretical results would at least help researchers to make the most efficient use possible of existing machines. Unfortunately theoretical work often stops short of providing everything which the practitioner requires. In this paper two communication problems transpose and all-to-all broadcast, are used to illustrate the additional effort required to make the theoretical practical. DOE

THE ZIPCODE MESSAGE-PASSING SYSTEM

A. Skjellum, S. G. Smith, C. H. Still, A. P. Leung (Syracuse Univ., NY.), and M. Morari (California Inst. of Tech., Pasadena.) 12 Nov. 1992 18 p Presented at the 6th SIAM Conference on Parallel Processing for Scientific Computing, Norfolk, VA, 21-24 Mar. 1993
(Contract W-7405-eng-48)
(DE93-011958; UCRL-JC-112022; CONF-930331-9) Avail: CASI HC A03/MF A01

Zipcode is a message-passing system developed originally by the first author, beginning at Caltech and continuing to-date. Zipcode was created to address features and issues absent in then-existing message-passing systems. Currently, Zipcode continues to serve as a vehicle to demonstrate high-level message-passing research concepts and, more importantly, to provide the basis for supporting vendor-independent scalable concurrent libraries; notably, the Multicomputer Toolbox. The basic assertion of Zipcode is that carefully managed, expressive message-passing is an effective way to program multicomputers and distributed computers, while low-level message passing is admittedly both error-prone and difficult. The purpose of Zipcode is to manage the message-passing process within parallel codes in an open-ended way. This is done so that large-scale software can be constructed in a multicomputer application, with reduced likelihood that software so constructed will conflict in its dynamic resource use, thereby avoiding potentially hard-to-resolve, source-level conflicts. Furthermore, the message-passing-notations provided are to reflect the algorithms and data organizations of the concurrent algorithms, rather than predefined typing strategies. Typing, while generic and easy-to-understand, proves too low-level to support manageable application development well. Notational abstractions provide a means for the user to incorporate information through which the Zipcode library may make optimizations when a code runs on systems with specific hardware features. Abstraction is therefore seen as a means to higher performance, and notation is seen as a means towards more understandable, easier-to-develop and maintain concurrent software. Context registry provides a 'social contract' within which multiple libraries and codes can coexist reasonably. DOE

THE PVM SYSTEMS: AN IN-DEPTH ANALYSIS AND DOCUMENTING STUDY. CONCISE EDITION

B. K. Grant and A. Skjellum Nov. 1992 20 p Presented at the 9th International Conference on Systems Engineering 1993, Las Vegas, NV, 14-16 Jul. 1993
(Contract W-7405-eng-48)
(DE93-011959; UCRL-JC-112016; CONF-930773-1) Avail: CASI HC A03/MF A01

The Parallel Virtual Machine (PVM) is a basic message-passing system for heterogeneous collections of networked computers, developed at Oak Ridge National Laboratory, University of Tennessee, and Emory University. This report is our 'third-party' effort to answer most common questions about PVM and to dispel many misconceptions regarding its capabilities. We strive to present an accurate assessment of the system, while adding our own opinions regarding the system, and offering a few suggestions for the future of the system. PVM version 2.4.1, the latest version at the time of the writing of this report, is summarized within this document; our forthcoming full report includes significantly more detailed information. Information on how to get the full report is included. DOE

A HETEROGENEOUS GRAPHICS PROCEDURE FOR VISUALIZATION OF MASSIVELY PARALLEL SOLUTIONS

1993 6 p Presented at the American Society of Mechanical Engineers (ASME) Fluids Engineering Conference, Washington, DC, 20-24 Jun. 1993
(Contract DE-AC04-76DP-00789)
(DE93-009628; SAND-93-0227C; CONF-930621-3) Avail: CASI HC A02/MF A01

Scientific visualization is playing an increasingly important role in the analysis and interpretation of massively parallel CFD simulations due to the enormous volume of data that can be generated on these machines. In this paper we will describe the development of a visualization technique based on a parallel analogue to the Marching Cubes algorithm. The algorithm has been developed for Multiple-Instruction, Multiple-Data (MIMD) massively parallel computers and is designed to take advantage of the heterogeneous programming capabilities of the MIMD architecture. We examine several different configurations and conclude that for producing animations the best one, in terms of both frame generation time and disk usage, is to run the two applications heterogeneously and send the resulting geometry description directly to a workstation for rendering, thereby totally eliminating the use of files from the animation process. HETEROGENEOUS SUPERCONCURRENT PARALLELISM (HeSCP) Professional Paper

R. F. Freund Mar. 1993 14 p
(AD-A265004) Avail: CASI HC A03/MF A01

HeSCP (Heterogeneous SuperConcurrent Parallelism, pronounced 'hee-skip') is the tuned use of diverse processors to solve distinct computational needs, in which codes or code portions are directed to the processor(s) best suited for their execution. Implicit in this definition is the idea that different tasks or different portions of these tasks indicate different architectural requirements or different balances of requirements. The processors themselves are generally parallel or other HPC machines. Typically the processors are used concurrently and it is often the case that tools and methodologies used for parallel and vector processing, e.g., code profiling, flow analysis, data dependencies, etc., can be extended to the larger, meta-parallel processor. The super in SuperConcurrent refers to the traditional supercomputing aims of HeSCP, as well as the heterogeneous concurrency superimposed on the various parallel processors, and finally the aim of superlinear performance from the tuned orchestration of the heterogeneous components. OPTIMAL CUBE-CONNECTED CUBE MULTIPROCESSORS Final Report
Xian-He Sun and Jie Wu Washington May 1993 17 p
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191463; ICASE-93-23; NAS 1.26:191463) Avail: CASI HC A03/MF A01

Many CFD (computational fluid dynamics) and other scientific applications can be partitioned into subproblems. However, in general the partitioned subproblems are very large. They demand high performance computing power themselves, and the solutions of the subproblems have to be combined at each time step. The cube-connect cube (CCCube) architecture is studied. The CCCube architecture is an extended hypercube structure with each node represented as a cube. It requires fewer physical links between nodes than the hypercube, and provides the same communication support as the hypercube does on many applications. The reduced physical links can be used to enhance the bandwidth of the remaining links and, therefore, enhance the overall performance. The concept and the method to obtain optimal CCCubes, which are the CCCubes with a minimum number of links under a given total number of nodes, are proposed. The superiority of optimal CCCubes over standard hypercubes was also shown in terms of the link usage in the embedding of a binomial tree. A useful computation structure based on a semi-binomial tree for divide-and-conquer type of parallel algorithms was identified. It was shown that this structure can be implemented in optimal CCCubes without performance degradation compared with regular hypercubes. The result presented should provide a useful approach to design of scientific parallel computers. Author (revised)

RELIABILITY ANALYSIS FOR FDDI DUAL HOMING NETWORKS
Gam D. Nguyen 7 May 1993 13 p
(AD-A266133; NRL/FR/5862-93-9552) Avail: CASI HC A03/MF A01

Fiber Distributed Data Interface (FDDI) is a high-speed, fiber-optic token network consisting of two counter-rotating rings. In addition to the fault tolerant level provided by the dual rings, the reliability of an FDDI network is enhanced by the use of station bypass switches or concentrators (CON's). A station equipped by a bypass switch is switched out of the ring when the station experiences a power failure. A CON facilitates the connection of stations to the ring and also switches out of the ring any faulty station connected to it. The use of reliable CON's to interconnect stations is the heart of the dual homing configuration. DTIC

SCALABLE SPIN LOCKS FOR MULTIPROGRAMMED SYSTEMS
Robert W. Wisniewski, Leonidas I. Kontothanassis, and Michael L. Scott Apr. 1993 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-92-J-1801; NSF CDA-88-227240; NSF CCR-90-05633; ARPA Order 8930)
(AD-A265007; TR-454) Avail: CASI HC A03

Synchronization primitives for large-scale multiprocessors need to provide low latency and low contention to achieve good performance. Queue-based locks (implemented in software with fetch and Phi instructions) can greatly reduce contention and improve overall performance by arranging for processors to spin only local locations. Unfortunately, queued locks exhibit poor behavior in the presence of multiprogramming: a process near the end of the queue, in addition to waiting for any process ahead of it in the queue. To solve this problem, we present two queue-based locks that recover from in queue preemption. The first employs the kernel interface of the NYU Symunix project. The second employs an extended interface that shares information in both directions across the user-kernel boundary. This results in simpler code and better performance. Experiments with these locks in both real and synthetic applications on SGI and KSR multiprocessors confirm the feasibility of high-performance software locks on systems that are both very large and multiprogrammed. The objectives of the High Performance Distributed Systems Architecture (HPDSA) project are to integrate very high bandwidth networks with heterogeneous computer architectures (including parallel and specialized processors) and support multiple programming models with this system. The driving forces for this project are user demands for high-performance computing coupled with the availability of gigabit and high bandwidth networking. Command and control applications are increasingly requiring the capabilities of both specialized processors and supercomputer-class machines. These resources are often concentrated at computer centers while the data sources and users of these systems are geographically distributed. By linking users, data sources, and systems together with high-speed networks and distributed operating systems, the quality of command and control information can be substantially improved and that information can be provided to more people. A high-performance distributed operating system must satisfy a number of design goals to accomplish our architectural objectives. Foremost, it must be capable of accommodating a wide variety of computers, networks, and programming languages. DTIC

DISTRIBUTED REAL-TIME SYSTEM DESIGN: THEORETICAL CONCEPTS AND APPLICATIONS Final Report
Lui Sha and Shirish S. Sathaye Mar. 1993 39 p
(Contract F19628-90-C-0003)
(AD-A265199; CMU/SEI-93-TR-02; ESC-TR-93-179) Avail: CASI HC A03/MF A01

Distributed real-time system design raises new theoretical issues and application challenges that are beyond those found in centralized systems. Rate monotonic scheduling (RMS) theory has been successfully applied in the scheduling of centralized systems. RMS and its generalizations have been adopted by national high technology projects such as the Space Station and it has recently been supported by major open standards such as the IEEE Futurebus+ and POSIX.4. In this paper, we describe the use of generalized rate monotonic scheduling theory for the design and analysis of a distributed real-time system. We view the recent extensions of the theory to distributed system scheduling, examine the architectural requirements for use of the theory, and finally provide an application example. DTIC

PROBLEM SPECIFIC ENVIRONMENTS FOR PARALLEL SYSTEMS Technical Report, Apr. 1991 - Jan. 1992
Loretta S. Auvil Apr. 1993 84 p
(AF Proj. 5581)
(AD-A266129; RL-TR-93-43) Avail: CASI HC A05/MF A01

Parallelism is one of the key components of large scale, high performance computing. Extensive use of parallelism has yielded a tremendous increase in the raw processing speed of high performance systems, but parallel problem solving remains difficult. These difficulties are typically solved by building software tools, such as parallel programming environments. Existing parallel programming environments are general purpose, using a broad paradigm. This report illustrates that problem specific environments are more beneficial than general purpose environments by making a case study comparison of two classes of problems. The simple class consists of two classic graph problems, namely, all pairs shortest path and connected components. The complex class consists of an elliptic partial differential equations solved via domain decomposition. The general purpose tools BUILD and SCHEDULE are used to solve each class. A problem specific environment for solving each class is then described. Comparisons between special purpose environments and general purpose environments show that the special purpose environments allow the user to concentrate on the problem, while general purpose environments force the user to think about mapping the problem to the environment rather than solving the problem in parallel. NETWORKS OF REAL-TIME PROCESSES
R. K. Yates Mar. 1993 17 p Presented at the 4th International Conference on Concurrency Theory, Hildesheim, Germany, 23-26 Aug. 1993
(Contract W-7405-eng-48)
(DE93-013049; UCRL-JC-113531; CONF-930898-1) Avail: CASI HC A03/MF A01

Networks of real-time processes prove that the input-output function computed by a network of asynchronous real-time processes is described by the unique fixed point of a network functional even though the components of the network may compute nonmonotonic functions. The techniques used are those of contractive functions on metric spaces rather than the usual Scott continuity on partial orders. Thus a well-known principle of Kahn is extended to an important model of parallel systems that has been resistant to the traditional approach using Scott continuity. DOE

THE APPLICABILITY OF NEURAL NETS FOR DECISION SUPPORT
E. H. L. Aarts (Philips Gloeilampenfabrieken N.V., Eindhoven, Netherlands.), J. Wessels (International Inst. for Applied Systems Analysis, Laxenburg, Austria.), and P. J. Zwietering Nov. 1992 24 p
(MEMO-COSOR-92-49; ETN-93-94328) Copyright Avail: CASI HC A03/MF A01

The aim of the work is to discuss the possible role of neural nets for decision support. The discussion is conducted along two connected lines. The first line regards the possibilities to solve combinatorial optimization problems with multilayered perceptrons. Particular attention is given to the required complexity of such neural nets. The second line regards the use of neural nets as a kind of black box decision mechanism for decision problems for which the underlying processes are difficult or not well understood. For direct use of the results of the first line it would be essential to have cheap neuro-based computing aids available. Even without the availability of such aids, the results are useful for supporting the second line. The second line has its value independent of the availability of special neural computing aids. It provides an alternative paradigm for decision support, which can be simulated on traditional computing equipment. ESA

TELEROBOTIC CONTROL OF A MOBILE COORDINATED ROBOTIC SERVER M.S. Thesis Annual Technical Report
Gordon Lee 10 Aug. 1993 75 p
(Grant NAG1-1283)
(NASA-CR-193465; NAS 1.26:193465) Avail: CASI HC A04/MF A01

The annual report on telerobotic control of a mobile coordinated robotic server is presented. The goal of this effort is to develop advanced control methods for flexible space manipulator systems. As such, an adaptive fuzzy logic controller was developed in which model structure as well as parameter constraints are not required for compensation. The work builds upon previous work on fuzzy logic controllers. Fuzzy logic controllers have been growing in importance in the field of automatic feedback control. Hardware controllers using fuzzy logic have become available as an alternative to the traditional PID controllers. Software has also been introduced to aid in the development of fuzzy logic rule-bases. The advantages of using fuzzy logic controllers include the ability to merge the experience and intuition of expert operators into the rule-base and that a model of the system is not required to construct the controller. A drawback of the classical fuzzy logic controller, however, is the many parameters needed to be turned off-line prior to application in the closed-loop. In this report, an adaptive fuzzy logic controller is developed requiring no system model or model structure. The rule-base is defined to approximate a state-feedback controller while a second fuzzy logic algorithm varies, on-line, parameters of the defining controller. Results indicate the approach is viable for on-line adaptive control of systems when the model is too complex or uncertain for application of other more classical control techniques. UNSUPERVISED SPLITTING RULES FOR NEURAL TREE CLASSIFIERS
Michael P. Perone and Nathan Intrator 17 May 1993 7 p
(Contract N00014-91-J-1316)
(AD-A264961) Avail: CASI HC A02/MF A01

This paper presents two unsupervised neural network splitting rules for use with CART-like neural tree algorithms in high dimensional data space. These splitting rules use an adaptive variance estimate to avoid some possible local minima which arise in unsupervised methods. We explain when the unsupervised splitting rules outperform supervised neural network splitting rules and when the unsupervised splitting rules outperform the standard node impurity splitting rules of CART. Using these unsupervised splitting rules lead to a nonparametric classifier for high dimensional space that extracts local features in an optimized way. DTIC

TASK PLANNING WITH UNCERTAINTY FOR ROBOTIC SYSTEMS Thesis
Tiehua Cao Mar. 1993 233 p
(Grant NAGw-1333)
(NASA-CR-193253; NAS 1.26:193253; CIRSSE-137) Copyright Avail: CASI HC A11/MF A03

In a practical robotic system, it is important to represent and plan sequences of operations and to be able to choose an efficient sequence from them for a specific task. During the generation and execution of task plans, different kinds of uncertainty may occur and erroneous states need to be handled to ensure the efficiency and reliability of the system. An approach to task representation, planning, and error recovery for robotic systems is demonstrated. Our approach to task planning is based on an AND/OR net representation, which is then mapped to a Petri net representation of all feasible geometric states and associated feasibility criteria for net transitions. Task decomposition of robotic assembly plans based on this representation is performed on the Petri net for robotic assembly tasks, and the inheritance of properties of liveness, safeness, and reversibility at all levels of decomposition are explored. This approach provides a framework for robust execution of tasks through the properties of traceability and viability. Uncertainty in robotic systems are modeled by local fuzzy variables, fuzzy marking variables, and global fuzzy variables which are incorporated in fuzzy Petri nets. Analysis of properties and reasoning about uncertainty are investigated using fuzzy reasoning structures built into the net. Two applications of fuzzy Petri nets, robot task sequence planning and sensor-based error recovery, are explored. In the first application, the search space for feasible and complete task sequences with correct precedence relationships is reduced via the use of global fuzzy variables in reasoning about subgoals. In the second application, sensory verification operations are modeled by mutually exclusive transitions to reason about local and global fuzzy variables on-line and automatically select a retry or an alternative error recovery sequence when errors occur. Task sequencing and task execution with error recovery capability for one and multiple soft components in robotic systems are investigated. Author

SAMPLE-DATA AND DISCRETE-TIME H2 OPTIMAL CONTROL
H. L. Trentelman (Groningen Rijksuniv., Netherlands.) and A. A. Stoorvogel
2 Dec. 1992 37 p
(MEMO-COSOR-92-53; ETN-93-94332) Copyright Avail: CASI HC A03/MF A01

The sampled data H(sub 2) optimal control problem is discussed. Given a linear time invariant continuous time system, the problem of minimizing the H(sub 2) performance over all sampled data controllers with a fixed sampling period can be reduced to a pure discrete time optimal control problem. This discrete time problem is always singular. The discrete time H(sub 2) optimal control problem in its full generality is studied. The results are applied to the singular discrete time H(sub 2) problem arising from the sampled data H(sub 2) problem. Conditions for the existence of optimal sampled data controllers are given. It is shown that the H(sub 2) performance of a continuous time controller can always be recovered asymptotically by choosing the sampling period sufficiently small. The optimal sampled data H(sub 2) performance is shown to converge to the continuous time optimal H(sub 2) performance as the sampling period converges to zero. ESA

THE DEVELOPMENT OF AN INTERACTIVE SYNTHESIS TOOL FOR INTELLIGENT CONTROLLERS OF MODULAR, RECONFIGURABLE ROBOTS Ph.D. Thesis
Catherine Glauber Ambrose 1992 318 p
Avail: Univ. Microfilms Order No. DA9309115

Intelligent controller design for modular, reconfigurable robot architectures was investigated. In robotic systems available today, the controller is the main limiting factor for enhanced performance. Numerous researchers are studying new controller architectures to allow for the implementation of advanced software, but few have targeted their research at reconfigurable designs. Focus was on the development of a modular controller architecture that can be reconfigured to meet the changing needs of new manipulators and new tasks. The dissertation work was divided into two parallel lines of research. First, a road map assessing the required technology for an intelligent controller was created. A complete model of robotic manipulators was developed which included the arm dynamics and the dynamics of the joint actuator systems. This model was used to determine the desired update rate for command signals from the robot controller. Second, a synthesis package was developed on a Silicon Graphics workstation to simulate controller architectures. This package allows the user to assemble computer components and select controller algorithms, and then evaluates the effectiveness of the design. Bottlenecks are easily identified and improved architectures can be rapidly created. This synthesis package was used to underscore the issues discussed in the road map. Author (revised)

A HIGH-SPEED OBJECT RECOGNITION CHIP BASED ON BIOLOGICALLY-REALISTIC HYBRID TEMPORAL PROCESSING ELEMENT Progress Report No. 1, 1 Apr. - 31 May 1993
26 May 1993 22 p
(Contract N00014-93-C-0118)
(AD-A265490) Avail: CASI HC A03/MF A01

The technical objective of this Phase 1 effort is to evaluate the feasibility of a binocular object recognition system for the integrated active vision system (AVS) currently under development at IRSI. The AVS based on a custom very large scale integration (VLSI) Hybrid Temporal Processing Element (HTPE) developed by IRSI (patent pending). Active vision implies that the image collection and processing operations form a single, integrated, adaptive system in which high-level processes, such as object recognition, can augment lower-level processes through feedback connections and can itself be controlled by higher levels. For example, the object recognition process can instruct the oscillating saccadic perception system to enhance the image resolution by a particular amount to assist in the object recognition process. Higher level perception systems can guide the object recognition processes by using expectations of what objects might be present in the image. Therefore, the AVS behaves as single image collection and processing system with coupled low-and high-level capabilities. DTIC

NEURAL NETWORK MODEL SELECTION USING ASYMPTOTIC JACKKNIFE ESTIMATOR AND CROSS-VALIDATION METHOD
Yong Liu 17 May 1993 9 p
(Contract N00014-91-J-1316)
(AD-A264960) Avail: CASI HC A02/MF A01

Two theorems and a lemma are presented about the use of jackknife estimator and the cross-validation method for model selection. Theorem 1 gives the asymptotic form for the jackknife estimator. Combined with the model selection criterion, this asymptotic form can be used to obtain the fit of a model. The model selection criterion we used is the negative of the average predictive likelihood, the choice of which is based on the idea of the cross-validation method. Lemma 1 provides a formula for further exploration of the asymptotics of the model selection criterion. Theorem 2 given an asymptotic form of the model selection criterion for the regression case, when the parameters optimization criterion has a penalty term. Theorem 2 also proves the asymptotic equivalence of Moody's model selection criterion (Moody, 1992) and the cross-validation method, when the distance measure between response y and regression function takes the form of a squared difference. A REGIONAL INVERSE EIGENVALUE PROBLEM: SOLUTION WITH APPLICATION IN CONTROL THEORY
M. A. Shalaby Oct. 1992 11 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-619666; IC-92/323) Avail: CASI HC A03 (US Sales Only)

A new procedure for the solution of the regional inverse eigenvalue problem is suggested and applied to the pole assignment problem of control theory. Algebraic inequalities are derived, they set bounds on the real and imaginary parts of the closed-loop matrix eigenvalues. As a result, these eigenvalues are located inside a prescribed rectangular region in the complex plane, which is better in real applications to control the system performance by a controller matrix which is computed in a more simpler way. MODEL REFERENCE ADAPTIVE CONTROL (MRAC) WITH APPLICATIONS TO ROBOTICS Ph.D. Thesis
Ricky Yin Jun Tam 1992 277 p
Avail. Univ. Microfilms Order No. DA9312081

Model reference adaptive control (MRAC) is investigated using a modified output error method (MOEM), a dual adaptive identifier/controller (DAIC), and a neuromorphic DAIC. It is shown that the adaptive law resulting from the error equation for MOEM does not require knowledge of the sign of the high frequency gain of the plant transfer function. Only a lower bound on the high frequency gain of the plant transfer function is necessary to assure the boundedness of all signals in the overall closed-loop system. No requirement of strictly positive realness is imposed on the reference model transfer function. A new dual adaptive identifier/controller is presented for model reference adaptive control. An inherent duality is shown to exist between adaptive identification and control in DAIC. An advantage of this duality in DAIC is that it enables the same adaptive algorithm to be used for both identification and control of an unknown plant. In the presence of an unbounded disturbance, an approach based on representing the unbounded disturbance functional in a series of bounded orthogonal functions is used for MRAC with a dual adaptive identifier/controller. A new method of extending the well known multilayered feed forward neural network with error back-propagation learning for the neuromorphic DAIC to perform on-line identification and control is also presented. It is demonstrated that the neuromorphic DAIC has a unique property, due to its duality: that an identical architecture of a modified multilayered feed forward neural network can be used for implementing both the neuromorphic identifier and the neuromorphic controller of DAIC. Parameter convergence and global stability of the overall closed-loop system resulting from the above three adaptive control methods are investigated. Proofs pertaining to the parameter convergence, global stability, and the derivation of the adaptive algorithms used for the adaptive control methods are included. Graphical results obtained from computer simulations of the adaptive control of a robotic manipulator system using the adaptive control methods studied are presented. Dissert. Abstr.

STATISTICAL AND OPTIMIZATION METHODS TO EXPEDITE NEURAL NETWORK TRAINING FOR TRANSIENT IDENTIFICATION
J. Reifman, E. J. Vitela, and J. C. Lee 1993 9 p Presented at the Meeting on Nuclear Plant Instrumentation, Control and Man-Machine Interface Technologies, Oak Ridge, TN, 18-21 Apr. 1993
(Contract W-31-109-eng-38)
(DE93-009985; ANL/RA/CP-77255; CONF-930401-12) Avail: CASI HC A02/MF A01

Two complementary methods, statistical feature selection and nonlinear optimization through conjugate gradients, are used to expedite feedforward neural network training. Statistical feature selection techniques in the form of linear correlation coefficients and information-theoretic entropy are used to eliminate redundant and non-informative plant parameters to reduce the size of the network. The method of conjugate gradients is used to accelerate the network training convergence and to systematically calculate the teaming and momentum constants at each iteration. The proposed techniques are compared with the backpropagation algorithm using the entire set of plant parameters in the training of neural networks to identify transients simulated with the Midland Nuclear Power Plant Unit 2 simulator. By using 25% of the plant parameters and the conjugate gradients, a 30-fold reduction in CPU time was obtained without degrading the diagnostic ability of the network. DOE

AN ADAPTIVE AND ROBUST CONTROL FOR MOTION COORDINATION OF TWO-COOPERATING ROBOT MANIPULATORS Ph.D. Thesis
Hyeung-Sik Choi 1993 136 p
Avail: Univ. Microfilms Order No. DA9312374

In a two-arm system, the dynamics of the two robot arms are highly coupled to each other, and parameters of the robot arms and an object are often unknown. For this reason, a good motion coordination of a two-arm system cannot be achieved by conventional control schemes. By incorporating the dynamics of the object into a dynamics of one arm, the order of the two-arm dynamics is reduced. Based on the reduced order model, three different control schemes are devised to have a good motion coordination of the two-arm systems: the first, under no parametric uncertainties, a force/position control scheme is devised, which coordinates a leader arm while regulating the coupling forces; second, when system parameters are unknown, an adaptive control scheme on the top of the force/position control scheme is devised to estimate the unknown parameters such that the parametric uncertainties are reduced or eliminated. However, the devised control scheme requires the feedback of the second derivative of the interacting forces and the existence of the non-singular inertia matrix which is a function of parameter estimates; third, to avoid this feedback, a new adaptive control scheme is devised. Also, to compensate coupling forces between two arms and bounded input disturbances, a robust control scheme is devised. Stability robustness analyses of the control schemes are shown based on Lyapunov Second Method. Numerical examples are also shown to simulate the proposed control schemes. According to the numerical examples, the control schemes show a good trajectory following under significant parameter errors. Dissert. Abstr.

One of the major unresolved sources of machine tool errors is thermal effects. Neural networks potentially offer a means of predicting errors in machine tool positioning due to thermal effects. These can then be used for compensation resulting in more accurate machining. This study demonstrates the feasibility of using artificial neural networks to predict thermally induced positioning errors on a turning center. The potential for application to other types of machine tools and implementation issues leading to commercialization are also discussed. DTIC

QUALITATIVE REASONING ABOUT THE PHYSICAL WORLD Final Report, Mar. 1985 - Dec. 1991
Kenneth D. Forbus Dec. 1992 7 p
(Contract N00014-85-K-0225)
(AD-A266117) Avail: CASI HC A02/MF A01

Qualitative physics is the subfield of artificial intelligence which investigates the kinds of representations and reasoning techniques which allow engineers, scientists, and just plain folks to understand and interact with the physical world. For example, Navy trainees learn to operate, maintain, and troubleshoot complex physical systems without needing advanced degrees in physics. Their common sense knowledge is augmented by their technical training and new skills, in order to carry out their tasks. To make computers that are capable of the same kind of flexible reasoning and learning regarding the physical world requires understanding common sense physics well enough to program it. DTIC

DERIVATION OF THREE CLOSED LOOP KINEMATIC VELOCITY MODELS USING NORMALIZED QUATERNION FEEDBACK FOR AN AUTONOMOUS REDUNDANT MANIPULATOR WITH APPLICATION TO INVERSE KINEMATICS
M. A. Unseren Apr. 1993 48 p
(Contract DE-AC05-84OR-21400)
(DE93-012823; ORNL/TM-12288) Avail: CASI HC A03/MF A01

The report discusses the orientation tracking control problem for a kinematically redundant, autonomous manipulator moving in a three dimensional workspace. The orientation error is derived using the normalized quaternion error method of Ickes, the Luh, Walker, and Paul error method, and a method suggested here utilizing the Rodrigues parameters, all of which are expressed in terms of normalized quaternions. The analytical time derivatives of the orientation errors are determined. The latter, along with the translational velocity error, form a closed loop kinematic velocity model of the manipulator using normalized quaternion and translational position feedback. An analysis of the singularities associated with expressing the models in a form suitable for solving the inverse kinematics problem is given. Two redundancy resolution algorithms originally developed using an open loop kinematic velocity model of the manipulator are extended to properly take into account the orientation tracking control problem. This report furnishes the necessary mathematical framework required prior to experimental implementation of the orientation tracking control schemes on the seven axis CESARm research manipulator or on the seven-axis Robotics Research K1207i dexterous manipulator, the latter of which is to be delivered to the Oak Ridge National Laboratory in 1993. Kierkeby (Aalborg Univ., Denmark.), and S. Kristensen (Aalborg Univ., Denmark.) 1993 19 p Presented at the 8th Scandanavian Conference on Image Analysis, Tromso, Norway, 25-28 May 1993
(Contract DE-AC05-84OR-21400)
(DE93-013280; CONF-9305198-1) Avail: CASI HC A03/MF A01

This paper describes some experiments in sensor-based mobile robot navigation conducted at Oak Ridge National Laboratory over the past several years. Two implemented systems are described. One uses a laser range camera as the sole sensor. The other uses, in addition, an array of sonars and a stereo vision system. We discuss a communication system for heterogeneous LAN-connected multiprocessor systems, useful in reasonably large development projects such as these. We also describe some work on the estimation of curvature in range images which introduces a new variational principle motivated by minimization of the change of curvature. Application of this principle is shown to produce results which are more desirable in some respects than those obtained using standard quadratic variation. DOE

(MEMO-1104; ETN-93-94317) Avail: CASI HC A03/MF A01

In the differential geometric framework, an exposition of Richardson-Nijenhuis and Froelicher-Nijenhuis brackets is given. The theory of deformations is exposed and deformations of a number of classical integral equations are constructed leading to recursion operators for these equations. Recursion operators play an important role in the theory of differential equations possessing infinite series of symmetries. They are shown to be of cohomological nature. A series of computational examples is exposed. Deformations of Burgers' equation including a nonlocal variable, KdV equation, nonlinear Schroedinger equation, and classical Boussinesq equation, all in the setting of coverings, are discussed. For these examples recursion operators are obtained from the results in a straight forward way. The basic theories concerning the geometry of differential equations, Froelicher-Nijenhuis brackets, C cohomologies, and coverings are reviewed. ESA

An algorithm for determining the number of Right Half Plane (RHP) zeros of an exponential polynomial is proposed. A short introduction on the well known circle criterion with special emphasis on exponential polynomials is given. With this result it is possible to determine the exact number of RHP zeros of an exponential polynomial with a graphical test. It is shown that only a part of the image of the imaginary axis has to be considered to determine the number of RHP zeros. A reliable method is given to search the imaginary axis for the crucial information. Variable step length is the key word here. An example to illustrate the method derived is given. Although it is not really faster, the method is far more reliable than the algorithm that was commonly used for this problem up to now. ESA

Symmetries have always fascinated human beings; they are found in nature, art, and architecture. Physicists, like other scientists have often used symmetries as a basis of their understanding of nature. When the dynamics is unknown, symmetries serve to delineate and define it. When the dynamics is known, symmetries are used to study structure. These two lectures review the theory and present understanding and status of two discrete space-time symmetries, namely parity (P) and time reversal (T). DOE

BALANCING OF THE NORMALIZED RIGHT COPRIME FACTORIZATION OF A NONLINEAR SYSTEM
J. M. A. Scherpen and A. J. vanderSchaft 27 Oct. 1992 15 p Sponsored by Dutch Systems and Control Theory Network, Netherlands
(MEMO-1096; ETN-93-94309) Avail: CASI HC A03/MF A01

A previously obtained method of balancing for stable nonlinear systems is extended to nonstable nonlinear systems in a similar way as this is done for linear systems. There exists a method of balancing for nonstable linear systems that makes use of the normalized right coprime factorization and the corresponding graph operator of the system. An extension of this method to nonstable nonlinear systems is proposed. The relation with balancing of the linearization is considered. Balancing of stable linear systems and balancing of the normal right coprime factorization of a linear system are reviewed. The concept of balancing for nonlinear systems and the linearization of this method of balancing are discussed. The results show that this matches with the linear theory. The normalized right coprime factorization of a nonlinear system and balancing based on this concept are considered. ESA

CYCLES THROUGH PARTICULAR SUBGRAPHS OF CLAW-FREE GRAPHS
H. J. Broersma and M. Lu (Academia Sinica, Beijing, China.) 3 Nov. 1992 10 p
(MEMO-1097; ETN-93-94310) Avail: CASI HC A02/MF A01

Let G be a 2 connected claw free graph on n vertices, and let H be a subgraph of G. It is proven that G has a cycle containing all vertices of H whenever alpha(sub 3)(H) is less than or equal to kappa (G), where alpha(sub 3)(H) denotes the maximum number of vertices of H that are pairwise at distance at least three in G, and kappa(G) denotes the connectivity of G. This result extends a result of Fournier and Thomassen and generalizes the result of Zhang that G is Hamiltonian if the degree sum of any k(G) + 1 pairwise nonadjacent vertices is at least n - k(G). ON OUTPUT LINEARIZATION OF OBSERVABLE DYNAMICS

Krzysztof Tchon (Technical Univ. of Wroclaw, Poland.) and Henk Nijmeijer Dec. 1992 41 p Sponsored by Univ. Twente, Enschede, Netherlands
(MEMO-1105; ETN-93-94318) Avail: CASI HC A03/MF A01

The problem of linearizing the observable dynamics by means of an output coordinate change is studied. The output linearization requires that the observability canonical form becomes linear after applying a suitable output diffeomorphism. The output linearization problem is completely solved. The problem of transforming a higher order differential equation in y variables to a linear form by means of a change of y coordinates is also solved. For both single-output and multi-output observed dynamics, necessary and sufficient conditions for the solvability of the above problems are derived. ESA

A classic result in universal algebra says that the class of subalgebras Sa(A) of a given algebra A constitutes an algebraic or compactly generated lattice with set theoretical inclusion as partial order. In this context, the following problems are considered: the existence of a maximal or the largest proper subalgebra of A that includes a given proper subalgebra B; and the existence of a maximal or the largest subalgebra of A which is incomparable with a given subalgebra B in Sa(A), which possess a lattice theoretic character. Both problems are studied at the level of algebraic lattices and, particularly, for the algebraic lattice Sa(A). The results were applied to formal language theory, i.e., A equal to the family of all languages. Some results of Ginsburg and Spanier on incomparable full Abstract Families of Languages (AFL) are extended to similar structures like full hyper-AFL's, full hyper(1)-AFL's, and prequasoids. An approach based on universal algebra and lattice theory enables the establishment of Ginsburg and Spanier like theorems for several types of language families. Formal language theory provides language families that may serve as (counter)examples in algebra. ESA

A SPECTRAL NODAL METHOD FOR DISCRETE ORDINATES PROBLEMS IN x,y GEOMETRY
R. C. deBarros and E. W. Larsen Jun. 1991 22 p In POLISH
(DE93-610128; IEN-23/91) Avail: CASI HC A03/MF A01 (US Sales Only)

A nodal method is proposed for the solution of S(sub N) problems in x,y-geometry. This method uses the Spectral Green's Function (SGF) scheme for solving the one-dimensional transverse-integrated nodal transport equations with no spatial truncation error. Thus, the only approximations in the x,y-geometry nodal method occur in the transverse leakage terms, as in diffusion theory. These leakage terms were approximated using a flat or constant approximation, and the resulting method is referred to as the SGF-Constant Nodal (SGF-CN) method. It is shown in numerical calculations that the SGF-CN method is much more accurate than other well-known transport nodal methods for coarse-mesh deep-penetration S(sub N) problems, even though the transverse leakage terms are approximated rather simply. VECTORIZING MATRIX OPERATIONS ARISING FROM PDE DISCRETIZATION ON 9-POINT STENCILS
J. G. Blom and J. G. Verwer Nov. 1992 22 p
(Grant CRG-92.05)
(CWI-NM-R9221; ETN-93-94149) Copyright Avail: CASI HC A03/MF A01

When solving a system of Partial Differential Equations (PDE) discretized on 9-point stencils over a nonrectangular domain, the linear systems that arise will have matrices with an irregular block structure. For these type of matrices, the vectorization, of the matrix-vector multiply and of the Incomplete LU (ILU) factorization and backsolve are discussed. The implemented matrix-vector multiply uses a block diagonal storage with indirect addressing. The performance of this routine is 1 result per clock cycle. For the ILU factorization and backsolve concurrence is obtained by reordering the computations using a variant of the hyperplane method. The performance of the standard hyperplane method reaches its optimum only for large systems, because the resulting vector length is half the number of modes in the x-direction. The performance of the indirect addressing version has a Megaflop rate that is a factor 1.5 smaller. The results show that, even for the original, not explicitly reordered, version the gain in computational time compared with the general purpose routines of the Sparse Linear Algebra Package (SLAP) library is significant, especially for the factorization. COMPLEX FUNCTIONS IN QUEUEING THEORY
J. W. Cohen Sep. 1992 22 p Sponsored in part by EEC
(CWI-BS-R9219; ETN-93-94150) Copyright Avail: CASI HC A03/MF A01

The background of an approach for solving the waiting time process problem for the GI/G/1 single server model is discussed. The Pollaczek's analysis of the GI/G/1 queueing model is reviewed. Techniques from the theory of complex functions constitute the core of his analysis. The advances in probability theory and in the theory of boundary value problems for analytic functions, which became known in the third quarter of our century have provided a wider context for the analysis of the GI/G/1 queueing model. For the time dependent as well as the stationary case this approach leads to the formulation of Riemann boundary value problems. The analysis of it for the stationary case is exposed and its solution is derived under slightly weaker conditions than originally considered by Pollaczek. ESA

LARGE TIME-STEP STABILITY OF EXPLICIT ONE-DIMENSIONAL ADVECTION SCHEMES
B. P. Leonard May 1993 30 p
(Contract NCC3-233; RTOP 505-90-5K)
(NASA-TM-106203; ICOMP-93-14; E-7867; NAS 1.15:106203) Avail: CASI HC A03/MF A01

There is a wide-spread belief that most explicit one-dimensional advection schemes need to satisfy the so-called 'CFL condition' - that the Courant number, c = udelta(t)/delta(x), must be less than or equal to one, for stability in the von Neumann sense. This puts severe limitations on the time-step in high-speed, fine-grid calculations and is an impetus for the development of implicit schemes, which often require less restrictive time-step conditions for stability, but are more expensive per time-step. However, it turns out that, at least in one dimension, if explicit schemes are formulated in a consistent flux-based conservative finite-volume form, von Neumann stability analysis does not place any restriction on the allowable Courant number. Any explicit scheme that is stable for c is less than 1, with a complex amplitude ratio, G(c), can be easily extended to arbitrarily large c. The complex amplitude ratio is then given by exp(-(Iota)(Nu)(Theta)) G(delta(c)), where N is the integer part of c, and delta(c) = c - N (less than 1); this is clearly stable. The CFL condition is, in fact, not a stability condition at all, but, rather, a 'range restriction' on the

'pieces' in a piece-wise polynomial interpolation. When a global view is taken of the interpolation, the need for a CFL condition evaporates. A number of well-known explicit advection schemes are considered and thus extended to large delta(t). The analysis also includes a simple interpretation of (large delta(t)) total-variation-diminishing (TVD) constraints.

BOUNDARY ELEMENT METHOD FOR EIGENVALUE PROBLEMS OF THIN PLATES M.S. Thesis
Ofer Weiss Aug. 1991 134 p In HEBREW
(ITN-93-85199) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

The Boundary Element Method is a numerical method that can be used to solve elastodynamic problems by means of boundary integrals. In this work the method is implemented for calculating the natural frequencies of thin plates, taking into account the influence of internal forces. In addition, a method is developed for continuous plate analysis, in which the problem comprises several fields of different thickness, with the inclusion of internal supports. The solution is achieved by replacing the differential equation with an integral equation by means of the Rayleigh-Green second identity and the appropriate Green's functions. A dynamic Green's function is used, based on Henkel's first function of the zeroth order. The numerical procedure includes the discretization of the integral which leads to a matrix. The natural frequencies are obtained using a local minimum search of the determinant. Several examples are presented and the results are compared with analytical and with numerical solutions. The good agreement obtained illustrates the effectiveness of the method presented in this thesis.

CONVERGENCE THEOREMS FOR A CLASS OF NONLINEAR MAPS IN UNIFORMLY SMOOTH BANACH SPACES
C. E. Chidume and M. O. Osilike (Nigeria Univ., Nsukka.) May 1992 10 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE92-641347; IC-92/91) Avail: CASI HC A02 (US Sales Only)

Let K be a nonempty closed and convex subset of a real uniformly smooth Banach space, E, with modulus of smoothness of power type q greater than 1. Let T be a mapping of K into itself, T is an element of C (in the notion of Browder and Petryshyn; and Rhoades). It is proved that the Mann iteration process, under suitable conditions, converges strongly to the unique fixed point of T. If K is also bounded, then the Ishikawa iteration process converges to the fixed point of T. While our theorems generalize important known results, our method is also of independent interest. DOE

FINITE DIFFERENCE SCHEMES FOR LONG-TIME INTEGRATION Final Report
Zigo Haras (Weizmann Inst. of Science, Rehovoth, Israel.) and Shlomo Taasan (Weizmann Inst. of Science, Rehovoth, Israel.) Washington Jun. 1993 33 p Submitted for publication
(Contracts NAS1-19480; NAS1-18605; RTOP 505-90-52-01)
(NASA-CR-191471; NAS 1.26:191471; ICASE-93-25) Avail: CASI HC A03/MF A01

Finite difference schemes for the evaluation of first and second derivatives are presented. These second order compact schemes were designed for long-time integration of evolution equations by solving a quadratic constrained minimization problem. The quadratic cost function measures the global truncation error while taking into account the initial data. The resulting schemes are applicable for integration times fourfold, or more, longer than similar previously studied schemes. A similar approach was used to obtain improved integration schemes. THE D-EDGE SHORTEST-PATH PROBLEM FOR A MONGE GRAPH
W. W. Bein (New Mexico Univ., Albuquerque.), L. L. Larmore (California Univ., Riverside.), and J. K. Park 14 Jul. 1992 10 p Presented at the Fourth Annaul ACM-SIAM Conference on Discrete Algorithms, Austin, TX, 25-27 Jan. 1993
(Contract DE-AC04-76DP-00789)
(DE93-009828; SAND-92-1724C; CONF-930194-1) Avail: CASI HC A02/MF A01

A complete edge-weighted directed graph on vertices 1,2,...,n that assigns cost c(i,j) to the edge (i,j) is called Monge if its edge costs form a Monge array, i.e., for all i less than k and j less than l, c(ij) + c(k,l) less than or = c(i,l) + c(k,j). One reason Monge graphs are interesting is that shortest paths can be computed quite quickly in such graphs. In particular, Wilber showed that the shortest path from vertex 1 to vertex n of a Monge graph can be computed in O(n) time, and Aggarwal, Klawe, Moran, Shor, and Wilber showed that the shortest d-edge 1-to-n path (i.e., the shortest path among all 1-to-n paths with exactly d edges) can be computed in O(dn) time. This paper's contribution is a new algorithm for the latter problem. Given certain assumptions, our algorithm runs in O(n(1 + 1g(U/L))) time. Thus, when d is much greater than 1 + 1g(U/L), our algorithm represents a significant improvement over Aggarwal et al.'s O(dn)-time algorithm. We also present several applications of our algorithm; they include length-limited Huffman coding, finding the maximum-perimeter d-gon inscribed in a given convex n-gon, and a digital signal compression problem. Improvements are presented for three iterative methods used for obtaining solutions of large sets of linear equations having symmetric, positive definite, yet sparse coefficient matrices. The investigated iterative methods are the incomplete approximate factorization procedure, conjugate gradient method, and Chebyshev semi-iterative method. Boundary-value problems of three dimensional descretized elliptic differential equations are solved with these methods, with the calculated results being subsequently compared using the resultant convergent rate. QUANTUM SOLITONS WITH CYLINDRICAL SYMMETRY
N. M. Chepilko, A. P. Kobushkin, and A. I. Syamtomov 1992 18 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-617659; ITP-92-28) Avail: CASI HC A03 (US Sales Only)

Soliton solutions with cylindrical symmetry are investigated within the nonlinear (sigma)-model disregarding the Skyrme-stabilized term. The solitons are stabilized by quantization of collective breathing mode and collapse in the h/2(pi) yields 0 limit. It is shown that for such stabilization mechanism the model, apart from solitons with integer topological number B, admits the solitons with half-odd B. The solitons with integer B have standard spin-isospin classification, but the B=1/2 solitons are shown to be characterized by spin, isospin and additional 'momentum'. DOE

DETECTING NON-LINEARITIES IN STATIONARY TIME SERIES
F. Takens 1992 31 p
(W-9223; ETN-93-94350) Copyright Avail: CASI HC A03/MF A01

The results concerning the question of how to decide whether a given stationary time series is adequately described by a linear stochastic model or contains non linearities are surveyed . In particular, it is considered whether a given time series shows an indication that it is not adequately described by a linear model. Some concepts of (chaotic) dynamical systems and the time series which they can produce are reviewed. The evolutions of a dynamical, system with finite dimensional state space, are considered as deterministic evolutions. The spectral theory of linear stochastic systems, their optimal predictors and the relation of these predictors with time series from dynamical systems, are reviewed. The time series produced by such stochastic systems are considered as the prototype of random time series. In an numerical example, it is shown how the deterministic structure becomes less recognizable in the residues. ESA

FINDING MINIMUM-QUOTIENT CUTS IN PLANAR GRAPHS
J. K. Park and C. A. Phillips 18 Nov. 1992 12 p Presented at the Association for Computing Machinery Symposium on the Theory of Computing, San Diego, CA, May 1993
(Contract DE-AC04-76DP-00789)
(DE93-011675; SAND-92-2585C; CONF-9305153-3) Avail: CASI HC A03/MF A01

Given a graph G = (V,E) where each vertex v element of V is assigned a weight w(v) and each edge e element of E is assigned a cost c(e), the quotient of a cut partitioning the vertices of V into sets S and (bar-S) is c(S,bar-S)/min(w(S),w(S)), where c(S,(bar-S)) is the sum of the costs of the edges crossing the cut and w(S) and w(bar-S) are the sum of the weights of the vertices in S and (bar-S), respectively. The problem of finding a cut whose quotient is minimum for a graph has in recent years attracted considerable attention. It has been shown that an algorithm (exact or approximation) for the minimum-quotient-cut problem can be used to obtain an approximation algorithm for the more famous minimum-b-balanced-cut problem, which requires finding a cut (S,bar-S) minimizing c(S,bar-S) subject to the constraint bW less than or equal to w(S) less than or equal to (1 - b)W, where W is the total vertex weight and b is some fixed balance in the range 0 less than bless than or equal to 1/2. Unfortunately, the minimum-quotient-cut problem is strongly NP-hard for general graphs, and the best polynomial-time approximation algorithm known for the general problem guarantees only a cut whose quotient is at most O(lg n) times optimal, where nis the size of the graph. However, for planar graphs, the minimum-quotient-cut problem appears more tractable, as Rao has developed several efficient approximation algorithms for the planar version of the problem capable of finding a cut whose quotient is at most some constant times optimal. In this paper, we improve Rao's algorithms, both in terms of accuracy and speed. As our first result, we present two pseudopolynomial-time exact algorithms for the planar minimum-quotient-cut problem. As Rao's most accurate approximation algorithm for the problem--also a pseudopolynomial-time algorithm--guarantees only a 1.5-times-optimal cut, our algorithms represent a significant advance. DOE

BAYESIAN MODEL FOR PICTORIAL DATA FUSION OF SATELLITE IMAGE M.S. Thesis [USO DA TEORIA DE ESTIMACAO BAYESIANA NA FUSAO DE DADOS DE SATELITES]
Ana LuciaBezerraCandeias 1992 151 p In PORTUGESE
(INPE-5457-TDI/499) Avail: CASI HC A08/MF A02

Pictorial data fusion is the denomination of a set of techniques for generating synthetic images from the combination of primary images, by attempting to preserve the best characteristics from each primary image. In this dissertation, a Bayesian model for pictorial data fusion is proposed, based on the work of Brum (1989). As an example, such a model is applied to the image data fusion of SPOT satellite images. A comparison between the proposed technique with others that were presented in the literature is made. The Bayesian model has the advantage of offering the potential for adaptation to the local characteristics of the images in the synthesis process, besides its formal statistical formulation.

A comprehensive review of optimization methods for solving separable nonlinear Least Squares (LS) problems, which usually arise in array processing or interpolation problems, is proposed. The problem formulation is carried out for both single and multiple data vector processing. In addition to conventional optimization techniques (e.g. conjugate gradient, BFGS,...), the Gauss-Newton (GN) method, generally preferred for resolving LS problems, is introduced in case of separation scheme. Then, three different 'versions' of GN algorithm are derived. A series of numerical tests enables the illustration of the superiority of Kaufman's algorithm, in comparison with other GN algorithms or conventional optimization methods. Finally, alternative optimization methods such as, Alternating Projection Method or a nondeterministic method called Fast Simulated Annealing are presented, the main feature of the latest being to enable the escape from local minima and therefore possibly improve the global convergence of the search. DEVELOPMENT OF GENERIC FIELD CLASSES FOR FINITE ELEMENT AND FINITE DIFFERENCE PROBLEMS
D. A. Verner, G. L. Heileman, K. G. Budge, and A. C. Robinson 1993 10 p Presented at the Object-Oriented Numerics Conference, Sunriver, OR, 25-27 Apr. 1993
(Contract DE-AC04-76DP-00789)
(DE93-011678; SAND-93-0767C; CONF-9304114-4) Avail: CASI HC A02/MF A01

This paper considers the development of a reusable object-oriented array library, as well as the use of this library in the construction of finite difference and finite element codes. The classes in this array library are also generic enough to be used to construct other classes specific to finite difference and finite element methods. The authors demonstrate the usefulness of this library by inserting it into two existing object-oriented scientific codes developed at Sandia National Laboratories. One of these codes is based on finite difference methods, while the other is based on finite element methods. Previously, these codes were separately maintained across a variety of sequential and parallel computing platforms. The use of object-oriented programming allows both codes to make use of common base classes. This offers a number of advantages related to optimization and portability. Optimization efforts, particularly important in large scientific codes, can be focused on a single library. Furthermore, by encapsulating machine dependencies within this library, the optimization of both codes on different architectures will only involve modification to a single library.

Multigrid methods are good candidates for the resolution of the system arising in numerical fluid dynamics. However, the question is to know if those algorithms which are efficient for the Poisson equation on structured meshes will still apply well to the Euler and Navier-Stokes equations on unstructured meshes. The study of elliptic problems leads us to define the conditions where a full multigrid strategy has O(N) complexity. The aim of this paper is to build a comparison between the elliptic theory and practical CFD problems. First, as an introduction, we will recall some basic definitions and theorems applied to a model problem. The goal of this section is to point out the different properties that we need to produce an FMG algorithm with O(N) complexity. Then, we will show how we can apply this theory to the fluid dynamics equations such as Euler and Navier-Stokes equations. At last, we present some results which are 2nd-order accurate and some explanations about the behavior of the FMG process. Author (revised)

DIRECT SOLUTION OF THE MATHEMATICAL ADJOINT EQUATIONS FOR AN INTERFACE CURRENT NODAL FORMULATION
T. A. Taiwo, W. S. Yang, and H. S. Khalil 1993 15 p Presented at the International Topical Meeting on Mathematical Methods and Supercomputing in Nuclear Applications (M&C+SNA '93), Karlsruhe (Germany), 19-23 Apr. 1993
(Contract W-31-109-eng-38)
(DE93-009961; ANL/RA/CP-76759; CONF-930404-10) Avail: CASI HC A03/MF A01

A numerical method for directly computing the mathematical adjoint flux moments and partial currents for the hexagonal-Z geometry interface current nodal formulation in the DIF3D code is described. The new scheme is developed as an alternative to an existing scheme that employs a similarity transformation of the physical adjoint solution to compute the mathematical adjoint. Whereas the existing scheme is rigorous only when the flat transverse-leakage approximation is employed, this new scheme is exact for all leakage approximations in the DIF3D nodal method. In the new scheme, adjoint nodal equations whose form is very similar to that of the forward nodal equations are derived by employing linear combinations of the adjoint partial currents as computational unknowns in the adjoint equations. This enables the use of the forward solution algorithm with only minor modifications for solving the mathematical adjoint equations. By using the new scheme as a reference method, it is shown numerically that while the results computed with the existing scheme are approximate, they are sufficiently accurate for calculations of global and local reactivity changes resulting from coolant voiding in a liquid metal reactor. (DE93-010195; DOE/ER-40614/25) Avail: CASI HC A03/MF A01

I develop a diagrammatic method for calculating chiral logarithms in the quenched approximation. While not rigorous, the method is based on physically reasonable assumptions which can be tested by numerical simulations. At the leading order in the chiral expansion, the reseults are as follows: (1) there are no chiral logarithms in quenched f(sub (pi)) m(sub u) = m(sub d); (2) the chiral logarithms in B(sub K) and related kaon B-parameters are, for m(sub d) = m(sub s) the same in the quenched approximation as in the full theory; and (3) for m(sub(pi)) and the condensate, there are extra chiral logarithms due to loops containing the eta('), which lead to a peculiar non-analytic dependence of these quantities on the bare quark mass. I discuss how there is a predictable finite volume dependence associated with each chiral logarithm. I compare the resulting predictions with numerical results; for most quantities the expected volume dependence is smaller than the errors, but for B(sub V) and B(sub A) there is an observed dependence which is consistent with the predictions. (DE93-619724; WIS-PH-92-86) Avail: CASI HC A03 (US Sales Only)

We discuss a new class of toroidal boundary conditions for one-dimensional quantum Hamiltonian with S(sub n) symmetry which are related to two-dimensional n-state Potts models in the extreme anisotropic Hamiltonian limit. At their self-dual point (a point were a second-order phase transition occurs for n=2,3,4) the duality transformation is shown to be an additional symmetry giving rise to a new class of 'duality twisted' toroidal boundary conditions. This corresponding Hamiltonians are given in terms of generators of the periodic Temprely-Lieb algebra with an odd number of generators. We discuss as an example the critical Ising model. Here the complete spectrum for the new boundary conditions can be obtained from a projection mechanism in the spin-1/2 XXZ Heisenberg chain. DOE

SUMMATION BY PARTS, PROJECTIONS, AND STABILITY
Pelle Olsson Jun. 1993 64 p Presented at the 1993 SIAM Annual Meeting, Philadelphia, PA, 12-16 Jul. 1993
(Contract NAS2-13721)
(NASA-CR-194290; NAS 1.26:194290; RIACS-TR-93-04) Avail: CASI HC A04/MF A01

We have derived stability results for high-order finite difference approximations of mixed hyperbolic-parabolic initial-boundary value problems (IBVP). The results are obtained using summation by parts and a new way of representing general linear boundary conditions as an orthogonal projection. By slightly rearranging the analytic equations, we can prove strict stability for hyperbolic-parabolic IBVP. Furthermore, we generalize our technique so as to yield strict stability on curvilinear non-smooth domains in two space dimensions. Finally, we show how to incorporate inhomogeneous boundary data while retaining strict stability. Using the same procedure one can prove strict stability in higher dimensions as well. ON A CLASS OF TWO-DIMENSIONAL NEAREST NEIGHBORING RANDOM WALKS
J. W. Cohen Sep. 1992 30 p Sponsored in part by EEC
(CWI-BS-R9220; ETN-93-94151) Copyright Avail: CASI HC A03/MF A01

For positive recurrent nearest neighboring, semi-homogeneous random walks on the lattice (0,1,2,...,) x (0,1,2,...), the bivariate generating function of the stationary distribution is analyzed for the case where one-step transitions to the north, north-east and east at interior points of the state space all have zero probability. It is shown that this generating function can be represented by meromorphic functions. The construction of this representation is exposed for a variety of one-step transition vectors at the boundary points of the state space. The model of the nearest neighboring random walk is defined by its one-step transition vector at interior and at the boundary points of the state space. The poles are shown to be the only singularities of the analytic continuations. ESA

IMPRECISE HIGHEST DENSITY REGIONS RELATED TO INTERVALS OF MEASURES
Dec. 1992 17 p
(MEMO-COSOR-92-54; ETN-93-94333) Copyright Avail: CASI HC A03/MF A01

The theory of intervals of measures enables the use of a set of possible probability density functions for a random variable. The concept of highest density regions is generalized for situations where lack of perfect knowledge about the distribution of a random variable is represented by intervals of measures. An imprecise highest density region is defined together with a theorem that implies that such a region is equal to a highest density region for one particular probability density function. This result can be used within the theory of imprecise probabilities, as for sensitivity analysis with regard to the distribution of a random variable. In the Bayesian theory of statistics highest density regions play an important role. ESA

(AD-A265250; AFOSR-93-0359TR) Avail: CASI HC A03/MF A01

Research was carried out in a number of areas of multivariate analysis. New methods have been proposed in the theory of M-estimation to safeguard against outliers. Asymptotic distributions have been derived under a minimal set of assumptions. Bootstrap techniques are extended to nonstandard situations. Theoretical and computational aspects of bootstrap are reviewed. Exact tests have been developed to test the significance of parent-offspring correlations. New methods have been devised for multitarget tracking. The new methods are found to be satisfactory as they depend on minimal assumptions and involve simpler computational algorithms. In the area of probability, Edgeworth expansions have been extended to cover the cases where some of the variables are not continuous, which is considered as a major advance from the point of view of practical applications. A new differential geometric structure of a statistical model is proposed which is more general and more informative than those considered earlier. The methods are applied to study properties of estimates of parameters. DTIC

GENERALIZED MANDELBROT RULE FOR FRACTAL SECTIONS Final Report
L. V. Meisel Apr. 1993 14 p
(AD-A266010; ARCCB-TR-93016) Avail: CASI HC A03/MF A01

Mandelbrot's rule for sections is generalized to apply to the Hentschel and Procaccia fractal dimension at arbitrary q and on arbitrary sections. It is shown that for almost all (n-m)-dimensional sections, D(sup n)(q) = D(n-m)(q) + m, where the D(sup r)(q) are box-counting Hentschel and Procaccia generalized fractal dimensions of r-dimensional sections of homogeneous fractal point sets in Rn. The rule is shown to apply for finite 'thickness' sections as well as 'true' sections. A more general form of the rule applicable to inhomogeneous fractal sets is also presented. DTIC

MARGINAL ALLOCATIONS IN THE CORE OF MINIMAL CHAIN-GAMES
Harry F. M. Aarts Nov. 1992 22 p
(MEMO-1103; ETN-93-94316) Avail: CASI HC A03/MF A01

A subclass of Minimum Cost Spanning Tree (MCST) games, called minimal chain games, are considered. For an arbitrary MCST game, one core element can be deduced directly from the underlying network, without first determining the data of the MCST game itself. This element is a marginal allocation corresponding to a specific ordering of the players. For minimal chain games, all marginal allocations can be deduced directly from the underlying network and a lot of marginal allocations turn out to be in the core. The main result gives necessary and sufficient conditions for an ordering of the players to guarantee that the corresponding marginal allocation in any minimal chain game is contained in the core of this game. THE STRUCTURE OF HILBERT FLAG VARIETIES
G. F. Helminck and A. G. Helminck (North Carolina State Univ., Raleigh.) Oct. 1992 42 p
(MEMO-1095; ETN-93-94308) Avail: CASI HC A03/MF A01

A geometric realization of infinite dimensional analogs of the finite dimensional representations of the general linear group is presented. These representations are of importance in quantum field theory and in the framework of integrable systems. This requires a detailed analysis of the structure of the flag varieties involved and the line bundles over them. In general the action of the restricted linear group can not be lifted to the line bundles and thus leads to central extensions of this group. It is determined exactly when these extensions are nontrivial. As an application, it is shown how the flag varieties occur in the latter context. ESA

THE MODULAR GROUP AND SUPER-KMS FUNCTIONALS

O. Stoytchev Oct. 1992 10 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-613029; IC-92/307) Avail: CASI HC A02 (US Sales Only)

We show that with every normal, faithful, self-adjoint functional (omega) on a von Neumann algebra A there is associated a canonical one-parameter sigma-weakly continuous *-automorphism group sigma(sup omega) (the analogue of the modular group) and a canonical Z(sub 2) grading Gamma on A, commuting with sigma(sup omega). The functional omega satisfies the weak super-KMS property with respect to sigma(sup omega) and Gamma. Furthermore, sigma(sup omega) and Gamma are unique pair of a sigma-weakly continuous one-parameter *-automorphism group and a grading of the algebra, commuting with each other, with respect to which omega is weakly super-KMS. GENERATING FUNCTION FOR CLEBSCH-GORDAN COEFFICIENTS OF THE SU(SUB Q)(2) QUANTUM ALGEBRA

S. S. Avancini and D. P. Menezes (Sao Paulo Univ., Brazil.) May 1992 14 p
(DE93-613093; IFT-P-016/92) Avail: CASI HC A03/MF A01 (US Sales Only)

Some methods have been developed to calculate the SU(sub q)(2) Clebsch-Gordan coefficients (CGC). Here we develop a method based on the calculation of Clebsch-Gordan generating function through the use of quantum algebraic coherent states. Calculating the su(sub q)(2) CGC by means of this generating function is an easy and straight-forward task. DOE

A SPECTRAL NODAL METHOD FOR THE SOLUTION OF THE Sn EQUATIONS IN x, y GEOMETRY FOR HIGHLY ABSORBING DEEP PENETRATION PROBLEMS

R. C. deBarros Sep. 1991 27 p
(DE93-613520; IEN-24/91) Avail: CASI HC A03/MF A01 (US Sales Only)

Presented here is an attempt to improve the accuracy of transport nodal methods applied to deep penetration transport problems in x,y-geometry. The resulting nodal method uses the Spectral Green's Function (SGF) scheme for solving the one-dimensional transverse-integrated S(sub N) exponential nodal equations with no spatial truncation error. Based on the physics of deep penetration problems, we approximate the transverse leakage terms by approximate exponential shape functions. We show in numerical calculation that the SGF-Exponential Nodal (SGF-Exp N) method is much more accurate than other transport nodal methods for coarse-mesh deep penetration problems, specially in highly absorbing media. A NEW APPROACH TO THE I/N-EXPANSION FOR THE DIRAC EQUATION

S. S. Stepanov and R. S. Tutik 1991 15 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-617647; ITP-91-94) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

The difficulties associated with application of the I/N-expansion to the Dirac equation have been resolved by applying the method of (h/2(pi))-expansion. This technique does not involve converting the initial equation into the Schroedinger-like or Klein-Gordon-like form. Obtained recurrence formulae have a simple form and allow one to find the I/N-corrections of an arbitrary order in any of the I/N-expansion scheme. The method restores the exact results for the Coulomb potential. DOE

THE TIME KEEPING SYSTEM FOR GPS BLOCK IIR c04
H. C. Rawicz, M. A. Epstein, and J. A. Rajan *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 5-16 (For primary document see N94-10963 01-70)
Avail: CASI HC A03/MF A04

The precision time keeping system (TKS) in the Global Positioning System (GPS), Block IIR satellites is designed to operate under severe natural and man made environmental conditions. The Block IIR TKS provides precise, autonomous time keeping for periods of up to seven months, without the intervention of the GPS Control Segment. The TKS is implemented using both linear and non-linear controls. The resulting TKS architecture uses a hybrid analog/digital phase locked loop (PLL). The paper provides details of the design and analysis of the TKS. The simulation techniques and the test bed activities used in performing the TKS design trade-offs are described. The effects of non-linear controls are analyzed using a TKS computer simulation of the PLL. The results from a hardware test bed are provided that verify desired TKS operation. The design criteria for the TKS computer simulation and the hardware test bed are indicated. The concepts for verification and testing of the TKS computer simulation and hardware test bed are presented. Author

PROGRESS ON GPS STANDARDIZATION c04
C. Thomas *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 17-30 (For primary document see N94-10963 01-70)
Avail: CASI HC A03/MF A04

It has been clear for some time that a desirable and necessary step for improvement of the accuracy of GPS time comparisons is to establish GPS standards which may be adopted by receiver designers and users. For this reason, a formal body, the CCDS Group on GPS Time Transfer Standards (CGGTTS), was created in 1991. It operates under the auspices of the permanent CCDS Working Group on TAI, with the objective of recommending procedures and models for operational time transfer by the GPS common-view method. It works in close cooperation with the Subcommittee on Time of the Civil GPS Service Interface Committee. The members of the CGGTTS have met in December 1991 and in June 1992. Following these two formal meetings, a number of decisions were taken for unifying the treatment of GPS short-term data and for standardizing the format of GPS data files. A formal CGGTTS Recommendation is now being written concerning these points. This paper relates on the work carried out by the CGGTTS. Author (revised)

US COAST GUARD GPS INFORMATION CENTER (GPSIC) AND ITS FUNCTION WITHIN THE CIVIL GPS SERVICE (CGS) c04
In NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 31-46 (For primary document see N94-10963 01-70)
Avail: CASI HC A03/MF A04

In 1987, the U.S. Department of Defense (DOD) formally requested that the U.S. Department of Transportation (DOT) take responsibility for providing an office that would respond to nonmilitary user needs for GPS information, data, and assistance. DOT accepted this responsibility and in February 1989, named the Coast Guard as their lead agency for the project. Since that time, the U.S. Coast Guard has worked with the U.S. Space Command to develop requirements and implement a plan for providing the requested interface with the civil GPS community. The Civil GPS Service (CGS) consists of four main elements: GPS Information Center (GPSIC) - provides GPS status information to civilian users of the system: Civil GPS Service Interface Committee (CGSIC) - established to identify civil GPS user technical information needs in support of the CGS program; Differential GPS (DGPS) - Coast Guard Research and Development Project; and PPS Program Office (PPSPO) - (Under development) will administer the program allowing qualified civil users to have access to the PPS signal. Details about the services these organizations provide are described.

COMPARISON OF GPS AND GLONASS COMMON-VIEW TIME TRANSFERS **c04**

W. Lewandowski, G. Petit, C. Thomas, G. T. Cherenkov (All-Union Research Inst. for Physical and Radiotechnical Measurements, Mendeleevo, USSR.), N. B. Koshelyaevsky (All-Union Research Inst. for Physical and Radiotechnical Measurements, Mendeleevo, USSR.), and S. B. Pushkin (All-Union Research Inst. for Physical and Radiotechnical Measurements, Mendeleevo, USSR.) *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 47-58 (For primary document see N94-10963 01-70)

Avail: CASI HC A03/MF A04

It was already shown than even with a simple daily averaging of GLONASS data at each site, continental GLONASS time transfer can be achieved at a level of several tens of nanoseconds. A further step is to carry out observations of GLONASS satellites by the common-view method. A comparison of GPS and GLONASS common-view time transfers between Russia and Western Europe are reported. At each site, a GPS receiver and a GLONASS receiver are connected to the same atomic clock. Both GPS receivers are of NBS type and the GLONASS receivers are of type A-724. As GPS common-view time transfer between Sevres and Mendeleevo is accomplished at a level of a few nanoseconds in precision, it gives an excellent reference with which to evaluate the performance of GLONASS common-view time transfer. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 65-72 (For primary document see N94-10963 01-70)

Avail: CASI HC A02/MF A04

Communications Research Laboratory (CRL) carried out a VLBI (Very Long Baseline Interferometer) experiment of the Pulsar 0329 plus 54 on November in 1992 between Kashima 26mPhi and Usuda 64mPhi. We got a correlation for it by using K-3 VLBI correlator which was developed by CRL. Though we observed a slow pulsar this time, we are going to make millisecond pulsar experiments by making good use of this result and by using K-4 correlator which is under developing in CRL. Its result will give us precise positions and proper motions of pulsars which are useful for obtaining precise pulsar timing. Author

AN ENSEMBLE PULSAR TIME **c90**

Gerard Petit, Claudine Thomas, and Patrizia Tavella (Instituto Elettrotecnico Nazionale, Galileo Ferraris, Turin, Italy.) *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 73-86 (For primary document see N94-10963 01-70)

Avail: CASI HC A03/MF A04

Millisecond pulsars are galactic objects that exhibit a very stable spinning period. Several tens of these celestial clocks have now been discovered, which opens the possibility that an average time scale may be deduced through a long-term stability algorithm. Such an ensemble average makes it possible to reduce the level of the instabilities originating from the pulsars or from other sources of noise, which are unknown but independent. The basis for such an algorithm is presented and applied to real pulsar data. It is shown that pulsar time could shortly become more stable than the present atomic time, for averaging times of a few years. Pulsar time can also be used as a flywheel to maintain the accuracy of atomic time in case of temporary failure of the primary standards, or to transfer the improved accuracy of future standards back to the present. EXPERIMENTAL COMPARISON OF TIME SYNCHRONIZATION TECHNIQUES BY MEANS OF LIGHT SIGNALS AND CLOCK TRANSPORT ON THE ROTATING EARTH

R. A. Nelson, C. O. Alley, J. D. Rayner, Y. H. Shih, C. A. Steggerda, B. C. Wang, and B. W. Agnew *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 87-104 (For primary document see N94-10963 01-70)

Avail: CASI HC A03/MF A04

An experiment was conducted to investigate the equivalence of two methods of time transfer in a noninertial reference frame: by means of an electromagnetic signal using laser light pulses and by means of the slow ground transport of a hydrogen maser atomic clock. The experiment may also be interpreted as an investigation of whether the one-way speeds of light in the east-west and west-east directions on the rotating earth are the same. The light pulses were sent from a laser coupled to a telescope at the NASA Goddard Optical Research Facility (GORF) in Greenbelt, Maryland to the U.S. Naval Observatory (USNO) in Washington, DC. The optical path was made possible by a 30-cm flat mirror on a water tower near GORF and a 25-cm flat mirror on top of the Washington National Cathedral near USNO. The path length was 26.0 km with an east-west component of 20.7 km. The pulses were reflected back over the same path by a portable array of corner cube reflectors. The transmission and return times were measured with a stationary Sigma Tau hydrogen maser and a University of Maryland event timer at GORF, while the times of reflection were measured with a similar maser and event timer combination carefully transported to USNO. Both timekeeping systems were housed in highly insulated enclosures and were maintained at constant temperatures to within +/- 0.1 C by microprocessor controllers. The portable system was also protected from shock and vibration by pneumatic supports. The difference delta(T) between the directly measured time of reflection according to the portable clock and the time of reflection calculated from the light pulse signal times measured by the stationary clock was determined. For a typical trip delta(T) is less than 100 ps and the corresponding limit on an anisotropy of the one-way speed of light is delta(c/c) is less than 1.5 x 10(exp -6). This the only experiment to date in which two atomic clocks were calibrated at one location, one was slowly transported to the other end of a path, and the times of transmission, reflection, and return of short light pulses sent in different directions along the path were registered. Author (revised)

PLANS TO IMPROVE THE EXPERIMENTAL LIMIT IN THE COMPARISON OF THE EAST-WEST AND WEST-EAST ONE-WAY LIGHT PROPAGATION TIMES ON THE ROTATING EARTH **c74**

C. O. Alley, T. E. Kiess, R. A. Nelson, A. V. Sergienko, Y. H. Shih, B. C. Wang, and F. M. Yang *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 105-112 (For primary document see N94-10963 01-70)

Avail: CASI HC A02/MF A04

The preceding paper describes the results so far (interrupted in the Spring of 1989 because of lack of funds) of an experiment comparing the one-way light propagation times on the surface of the rotating Earth. For the 20 Km path length component in the East-West direction the predicted difference between the opposite sense propagation times would be 160 ps, if the approximately 360 Km/s surface speed of the Earth gives effective light speeds of 3 x 10(exp 8) m/s +/- 360 m/s. This could lead to a prediction of the difference between the clock transport and the light pulse synchronization methods described in the preceding paper: delta(T) = 0.5 (160) = 80 ps. The current upper bound of approximately 100 ps for delta(T) is limited by poorly understood systematic errors. The most important seems to be intensity-dependent time delays in the remote light pulse avalanche photo-diode detector. This will be replaced by a continuously operating circular scan streak camera having single photon sensitivity and a time resolution of approximately 5 ps. (This camera has recently been developed by the Xian Institute of Optics and Precision Mechanics in the P.R.C.). Better isolation from shocks and vibration for the Sigma-Tau hydrogen maser during transport will be provided. It is hoped that delta(T) is less than 20 ps can be achieved. Author (revised)

LASSO OBSERVATIONS AT MCDONALD AND OCA/CERGA: A PRELIMINARY ANALYSIS

Ch. Veillet, P. Fridelance, D. Feraudy, Y. Boudon, P. J. Shelus (McDonald Observatory, Fort Davis, TX.), R. L. Ricklefs (McDonald Observatory, Fort Davis, TX.), and J. R. Wiant (McDonald Observatory, Fort Davis, TX.) *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 113-122 (For primary document see N94-10963 01-70)
Avail: CASI HC A02/MF A04

The Laser Synchronization from Synchronous Orbit (LASSO) observations between USA and Europe were made possible with the move of Meteosat 3/P2 toward 50 deg W. Two Lunar Laser Ranging stations participated into the observations: the MLRS at McDonald Observatory (Texas, USA) and OCA/CERGA (Grasse, France). Common sessions were performed since 30 Apr. 1992, and will be continued up to the next Meteosat 3/P2 move further West (planned for January 1993). The preliminary analysis made with the data already collected by the end of Nov. 1992 shows that the precision which can be obtained from LASSO is better than 100 ps, the accuracy depending on how well the stations maintain their time metrology, as well as on the quality of the calibration (still to be made.) For extracting such a precision from the data, the processing has been drastically changed compared to the initial LASSO data analysis. It takes into account all the measurements made, timings on board, and echoes at each station. This complete use of the data increased dramatically the confidence into the synchronization results. MIL-STDS AND PTTI: WHAT'S AVAILABLE AND WHAT NEEDS TO BE DONE

James A. Murray and Joseph D. White (Naval Research Lab., Washington, DC.) *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 123-136 (For primary document see N94-10963 01-70)
Avail: CASI HC A03/MF A04

The systems developer who needs Precise Time and Time Interval (PTTI) capability has relatively little guidance in the form of military standards, particularly for systems using atomic clocks or other sources of very precise time and frequency. The existing standards, including MIL-STD-188-115, MIL-F-2991(EC), and DOD-STD-1399 are discussed. These documents were written several years ago and do not always reflect current practice or take advantage of more recent technology improvements. User needs have also changed over the years and some of those needs such as more detailed time codes are not being met. We will summarize what's available and what's good and bad about it. The second part will make suggestions about what should be done in the future to promote and facilitate good PTTI design practice. Topics will include clock performance parameters, environmental considerations, time codes, signal isolation, and time dissemination. Author (revised)

PTTI-AIDED EPHEMERIS CALCULATION AND RAPID DATA LINK ACQUISITION FOR MANNED SPACE FLIGHT **c17**

Alfred Anderman *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 137-152 (For primary document see N94-10963 01-70)
Avail: CASI HC A03/MF A04

Complexity of future manned space flight mission control can be significantly reduced by integrating GPS, the PTTI source, into telemetry, tracking, and command (TT&C). Future telecommunications, space tracking electronic intelligence, metrology, navigation, and data acquisition will thereby be served, including: on-board ephemeris determination, reduced synchronization time for time division multiple access (TDMA) links, and in-flight clock calibration, increasing on-board autonomy and reducing ground support costs. Manned space transportation through the first quarter of the 21st century will probably depend on a mix of vehicles, including the Advanced Manned Launch System (AMLS), the Personnel Launch System (PLS), and continued use of the Shuttle Fleet. Precise Ephemeris is important on-board for mission success, status monitoring, also for rendezvous and docking. Use of GPS can eliminate ground based tracking/processing, enhancing autonomy and reducing communications bandwidth. GPS time can simplify complicated functions used in bandwidth efficient time division multiple access (TDMA) communications, such as: precise and realtime synchronization of receive reference timing, transmit-timing and acquisition control, unique synchronization word (UW) detection, and elastic buffering. High clock accuracy provides increased signal-to-noise (S/N) ratio during acquisition, permitting narrower acquisition frequency and time windows. Spaceborne systems requirements to provide capabilities such as: refinement of the GEM-72 gravity model based on satellite tracking observations from ATS-6 to GEOS-3, relativistic clock experiments, NASA crustal dynamics program for developing space geodetic techniques to study the earth's crust, its gravity field, and earthquake mechanisms, and multi-disciplinary space geodetic tracking for studying global climatic changes are also reviewed. UNDERWATER HYDROPHONE LOCATION SURVEY **c48**

Jack B. Cecil *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 153-158 (For primary document see N94-10963 01-70)
Avail: CASI HC A01/MF A04

The Atlantic Undersea Test and Evaluation Center (AUTEC) is a U.S. Navy test range located on Andros Island, Bahamas, and a Division of the Naval Undersea Warfare Center (NUWC), Newport, RI. The Headquarters of AUTEC is located at a facility in West Palm Beach, FL. AUTEC's primary mission is to provide the U.S. Navy with a deep-water test and evaluation facility for making underwater acoustic measurements, testing and calibrating sonars, and providing accurate underwater, surface, and in-air tracking data on surface ships, submarines, aircraft, and weapon systems. Many of these programs are in support of Antisubmarine Warfare (ASW), undersea research and development programs, and Fleet assessment and operational readiness trials. Most tests conducted at AUTEC require precise underwater tracking (plus or minus 3 yards) of multiple acoustic signals emitted with the correct waveshape and repetition criteria from either a surface craft or underwater vehicle. A LASER-COOLED CESIUM FOUNTAIN FREQUENCY STANDARD AND A MEASUREMENT OF THE FREQUENCY SHIFT DUE TO ULTRA-COLD COLLISIONS Abstract Only

Kurt Gibble, Steven Kasapi, and Steven Chu *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 159-162 (For primary document see N94-10963 01-70)
Avail: CASI HC A01/MF A04

A frequency standard based on an atomic fountain of cesium atoms may have an accuracy of 10(exp -16) due to longer interaction times and smaller anticipated systematic errors. All of the known systematic effects that now limit the accuracy of the Cs frequency standard increase either linearly or as some higher power of the atom's velocity. The one systematic frequency shift which is dramatically different is the frequency shift due to the collisions between the laser cooled atoms. At a temperature of a few micro-K, the de Broglie wavelength (lambda(sub deB) = h/p, where h is Planck's constant and p is the momentum of the atom) is much larger than the scale of the interatomic potential. Under these conditions the collision cross sections can be as large as (lambda(sub deB)(sup 2))/Pi and the frequency shift due to these collisions was recently calculated. In our Cs atomic fountain, we laser cooled and trapped 10(exp 10) Cs atoms in 0.4 s. By shifting the frequencies of the laser beams, the atoms were launched upwards at 2.5 m/s and a fraction of the atoms were optically pumped into the F=3 ground state. The unwanted atoms in the F=4 ground state were removed from the fountain with radiation pressure from a laser beam tuned to excite only those atoms. The Cs atoms in the F=3 state traveled ballistically upwards, were excited by the microwave cavity, and then returned back through the same cavity in the atomic fountain configuration. By varying the cold atom density, a density dependent shift of -12.9 +/- 0.7 mHz or -1.4 x 10-12 for an average fountain density of (2.7 +/- 1.5) 10(exp 9) atoms/cm(sup 3) was measured. DISCIPLINED RUBIDIUM OSCILLATOR WITH GPS SELECTIVE AVAILABILITY
Wayne P. Dewey *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 163-172 (For primary document see N94-10963 01-70)
Avail: CASI HC A02/MF A04

A U.S. Department of Defense decision for continuous implementation of GPS Selective Availability (S/A) has made it necessary to modify Rubidium oscillator disciplining methods. One such method for reducing the effects of S/A on the oscillator disciplining process was developed which achieves results approaching pre-S/A GPS. The Satellite Hopping algorithm used in minimizing the effects of S/A on the oscillator disciplining process is described, and the results of using this process to those obtained prior to the implementation of S/A are compared. Test results are from a TrueTime Rubidium based Model GPS-DC timing receiver. Author (revised)

A PRECISE GPS-BASED TIME AND FREQUENCY SYSTEM
Jack McNabb and Earl Fossler *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 173-184 (For primary document see N94-10963 01-70)
Avail: CASI HC A03/MF A04

An approach to implementing a compact, highly reliable and precise Master Time and Frequency subsystem usable in a variety of applications is described. These applications include, among others, Satellite Ground Terminals, Range Timing Stations, Communications Terminals, and Power Station Timing subsystems. All time and frequency output signals are locked to Universal Time via the GPS Satellite system. The system provides for continued output of precise signals in the event of GPS signal interruption from antenna or lead-in breakage or other causes. Cost/performance tradeoffs affecting system accuracy over the short, medium, and long term are discussed. A unique approach to redundant system design provides an architecture with the reliability advantage of triple-redundant majority voting and the cost advantages of dual-redundant elements. The system can be configured to output a variety of precise time and frequency signals and the design can be tailored to output as few, or as many, types and quantities of signals as are required by the application. POSSIBLE APPLICATIONS OF ATOMIC FREQUENCY STANDARDS WITH AN INTERNAL HIGH RESOLUTION DIGITAL SYNTHESIZER
E. Detoma and A. Stern (Time and Frequency Ltd., Holon, Israel.) *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 185-198 (For primary document see N94-10963 01-70)
Avail: CASI HC A03/MF A04

The applications of Atomic Frequency Standards with an internal synthesizer (thereafter referred as 'Synthesized Frequency Standards or Oscillators') with a special emphasis on the Rb oscillator are reviewed. A fractional frequency synthesizer, developed by SEPA, was incorporated in the Frequency Locked Loop of a TFL Rubidium Frequency Standard. This combination allows a frequency settability in steps of 1.5 x 10(exp -12) (optional 1 x 10(exp -13) over a range of 6 x 10(exp -9) without having to resort to change the C-field to tune the output frequency of the device. This capability, coupled to the excellent short term stability of the Rb frequency standard, opens new possibilities for time and frequency users in the various fields (time metrology, navigation, communication, etc.) in which stable frequency standards find their application. CAFS: A CESIUM ATOMIC FREQUENCY STANDARD FOR GPS BLOCK IIR
Jeffry A. Wisnia *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 199-208 (For primary document see N94-10963 01-70)
Avail: CASI HC A02/MF A04

Kernco, Inc. was selected to design the Cesium Atomic Frequency Standards (CAFS) for the GPS Block IIR NAVSTAR satellites. These spacecraft are scheduled to be launched in the mid-1990's to replenish and upgrade the existing constellation of Global Positioning System satellites. The Block IIR CAFS output frequency is 13.4003378 MHz, the 686th submultiple of the cesium atomic resonance frequency. Using an integer submultiple simplifies the design of the atomic frequency standard's rf multiplier circuits, eliminating the secondary frequency synthesizer needed in previous designs. The GPS Block IIR CAFS design, particularly the improvements made on our earlier Block II design is described. Test results are included. Author (revised)

STATUS OF LOCAL OSCILLATORS FOR OPERATING ULTRA-HIGH RESOLUTION FREQUENCY DISCRIMINATORS AS FREQUENCY STANDARDS
R. F. C. Vessot, E. M. Mattison, M. W. Levine, and R. L. Walsworth *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 209-220 (For primary document see N94-10963 01-70)
Avail: CASI HC A03/MF A04

The operation of new improved frequency standards based on new ultra-high-resolution frequency discriminators requires high stability local, or 'flywheel' oscillators. We review the spectral density of phase fluctuations of existing flywheel oscillators and the related time domain frequency stability of new and proposed cryogenically cooled oscillators suitable for this application. Presently used devices include the quartz crystal oscillator, the room-temperature actively oscillating atomic hydrogen (H) maser, and the superconducting maser oscillator. Future devices include the cryogenic H-maser and other cryogenic devices using resonators of superconducting metal or solid crystalline sapphire. The relation of the phase spectral density of these devices to the characteristics of present and proposed frequency discriminators based on trapped cooled ions and cold atoms is discussed in terms of their operation as frequency standards.

DEVELOPMENT OF A CRYOGENIC HYDROGEN MASER AT THE NPL
c36
R. Mossavati *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 221-230 (For primary document see N94-10963 01-70)
Avail: CASI HC A02/MF A04

A prototype Cold Hydrogen Maser (CHM) was being developed for the past year. The features of this CHM, which is designed to operate initially at 4.2 K, are the use of low loss alumina, and later sapphire, in the fabrication of the microwave cavity; possible use of superconductors for shielding; use of a cryogenic amplifier; possible coating material; and a reliable RF discharge circuit for the dissociation of hydrogen. A numerical simulation was performed to find the dimensions of the microwave cavity for the TE011 mode and the model was confirmed experimentally. The system will be used to test various wall coatings adsorbed on top of a PTFE buffer underlayer. The CHM is expected to be used as a flywheel frequency standard at the NPL with medium-term stability of one part in 10(exp 14) or better. Author (revised)

TWO WAY TIME TRANSFER RESULTS AT NRL AND USNO
Ivan J. Galysh and G. Paul Landis *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 231-242 (For primary document see N94-10963 01-70)
Avail: CASI HC A03/MF A04

The Naval Research Laboratory (NRL) has developed a two way time transfer modem system for the United States Naval Observatory (USNO). Two modems in conjunction with a pair of Very Small Aperture Terminal (VSAT) and a communication satellite can achieve sub nanosecond time transfer. This performance is demonstrated by the results of testing at and between NRL and USNO. The modems use Code Division Multiple Access (CDMA) methods to separate their signals through a single path in the satellite. Each modem transmitted a different Pseudo Random Noise (PRN) code and received the others PRN code. High precision time transfer is possible with two way methods because of reciprocity of many of the terms of the path and hardware delay between the two modems. The hardware description was given in a previous paper. Author (revised)

PERFORMANCES OF A DATE DISSEMINATION CODE ON TELEPHONE LINES USING COMMERCIAL MODEMS **c32**

F. Cordara, V. Pettiti, R. Quasso (Politecnico di Torino, Italy.), and E. Rubiola (Politecnico di Torino, Italy.) *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 243-254 (For primary document see N94-10963 01-70)

Avail: CASI HC A03/MF A04

A coded time/date information dissemination system (CTD), based on telephone lines and commercial modems, is now in its experimental phase in Italy at IEN. This service, born from a cooperation with other metrological laboratories (TUG, Austria, SNT, Sweden, VSL, The Netherlands), represents an attempt towards an European standardization. Some results of an experimental analysis in which a few modems were tested, both in laboratory conditions and connected to the telephone network, in order to evaluate the timing capability of the system are given. When the system is used in a one-way mode, in many practical cases the modems delay turns out to be the main factor which limits the accuracy, even more than the telephone line delays. If the two-way mode is used, the modems asymmetry, i.e., the delay difference between transmission and reception, is almost always the most important source of uncertainty, provided the link is not including a space segment. Comparing the widely used V.22 modems to the old V.21 ones, the latters turn out to be better both in delay time (30-100 ms V.22, and 7-15 ms V.21) and asymmetry (10-50 micro-s V.22, and 10 ms V.22). Time transfer accuracies of 10 micron-s (same turn) to 100 micro-s (long distance calls) were obtained in two-way mode with commercial V.21 modems. Author

TIMESET: A COMPUTER PROGRAM THAT ACCESSES FIVE ATOMIC TIME SERVICES ON TWO CONTINENTS **c61**

P. L. Petrakis *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 255-266 (For primary document see N94-10963 01-70)

Avail: CASI HC A03/MF A04

TimeSet is a shareware program for accessing digital time services by telephone. At its initial release, it was capable of capturing time signals only from the U.S. Naval Observatory to set a computer's clock. Later the ability to synchronize with the National Institute of Standards and Technology was added. Now, in Version 7.10, TimeSet is able to access three additional telephone time services in Europe - in Sweden, Austria, and Italy - making a total of five official services addressable by the program. A companion program, TimeGen, allows yet another source of telephone time data strings for callers equipped with TimeSet version 7.10. TimeGen synthesizes UTC time data strings in the Naval Observatory's format from an accurately set and maintained DOS computer clock, and transmits them to callers. This allows an unlimited number of 'freelance' time generating stations to be created. Timesetting from TimeGen is made feasible by the advent of Becker's RighTime, a shareware program that learns the drift characteristics of a computer's clock and continuously applies a correction to keep it accurate, and also brings .01 second resolution to the DOS clock. With clock regulation by RighTime and periodic update calls by the TimeGen station to an official time source via TimeSet, TimeGen offers the same degree of accuracy within the resolution of the computer clock as any official atomic time source. RIGHTIME: A REAL TIME CLOCK CORRECTING PROGRAM FOR MS-DOS-BASED COMPUTER SYSTEMS **c61**

G. Thomas Becker *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 267-276 (For primary document see N94-10963 01-70)

Avail: CASI HC A02/MF A04

A computer program is described which effectively eliminates the misgivings of the DOS system clock in PC/AT-class computers. RighTime is a small, sophisticated memory-resident program that automatically corrects both the DOS system clock and the hardware 'CMOS' real time clock (RTC) in real time. RighTime learns what corrections are required without operator interaction beyond the occasional accurate time set. Both warm (power on) and cool (power off) errors are corrected, usually yielding better than one part per million accuracy in the typical desktop computer with no additional hardware, and RighTime increases the system clock resolution from approximately 0.0549 second to 0.01 second. Program tools are also available which allow visualization of RighTime's actions, verification of its performance, display of its history log, and which provide data for graphing of the system clock behavior. The program has found application in a wide variety of industries, including astronomy, satellite tracking, communications, broadcasting, transportation, public utilities, manufacturing, medicine, and the military. MEASUREMENT METHODS AND ALGORITHMS FOR COMPARISON OF LOCAL AND REMOTE CLOCKS

Judah Levine *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 277-288 (For primary document see N94-10963 01-70)

Avail: CASI HC A03/MF A04

Several methods for characterizing the performance of clocks with special emphasis on using calibration information that is acquired via an unreliable or noisy channel is discussed. Time-domain variance estimators and frequency-domain techniques such as cross-spectral analysis are discussed. Each of these methods has advantages and limitations that will be illustrated using data obtained via GPS, ACTS, and other methods. No one technique will be optimum for all of these analyses, and some of these problems cannot be completely characterized by any of the techniques discussed. The inverse problem of communicating frequency and time corrections to a real-time steered clock are also discussed. Methods were developed to mitigate the disastrous problems of data corruption and loss of computer control. Author (revised)

ADVANCES IN TIME-SCALE ALGORITHMS **c61**

S. R. Stein *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 289-302 (For primary document see N94-10963 01-70)

Avail: CASI HC A03/MF A04

The term clock is usually used to refer to a device that counts a nearly periodic signal. A group of clocks, called an ensemble, is often used for time keeping in mission critical applications that cannot tolerate loss of time due to the failure of a single clock. The time generated by the ensemble of clocks is called a time scale. The question arises how to combine the times of the individual clocks to form the time scale. One might naively be tempted to suggest the expedient of averaging the times of the individual clocks, but a simple thought experiment demonstrates the inadequacy of this approach. Suppose a time scale is composed of two noiseless clocks having equal and opposite frequencies. The mean time scale has zero frequency. However if either clock fails, the time-scale frequency immediately changes to the frequency of the remaining clock. This performance is generally unacceptable and simple mean time scales are not used. First, previous time-scale developments are reviewed and then some new methods that result in enhanced performance are presented. The historical perspective is based upon several time scales: the AT1 and TA time scales of the National Institute of Standards and Technology (NIST), the A.1(MEAN) time scale of the US Naval observatory (USNO), the TAI time scale of the Bureau International des Poids et Measures (BIPM), and the KAS-1 time scale of the Naval Research laboratory (NRL). The new method was incorporated in the KAS-2 time scale recently developed by Timing Solutions Corporation. The goal is to present time-scale concepts in a nonmathematical form with as few equations as possible. Many other papers and texts discuss the details of the optimal estimation techniques that may be used to implement these concepts. Author (revised)

TIME SIGNAL DISTRIBUTION IN COMMUNICATION NETWORKS BASED ON SYNCHRONOUS DIGITAL HIERARCHY **c32**

Atsushi Imaoka and Masami Kihara *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 303-312 (For primary document see N94-10963 01-70)
Avail: CASI HC A02/MF A04

A new method that uses round-trip paths to accurately measure transmission delay for time synchronization is proposed. The performance of the method in Synchronous Digital Hierarchy networks is discussed. The feature of this method is that it separately measures the initial round trip path delay and the variations in round-trip path delay. The delay generated in SDH equipment is determined by measuring the initial round-trip path delay. In an experiment with actual SDH equipment, the error of initial delay measurement was suppressed to 30ns. Author

SYNOPSIS OF TIMING MEASUREMENT TECHNIQUES USED IN TELECOMMUNICATIONS **c32**
George Zampetti *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 313-326 (For primary document see N94-10963 01-70)
Avail: CASI HC A03/MF A04

Historically, Maximum Time Interval Error (MTIE) and Maximum Relative Time Interval Error (MRTIE) have been the main measurement techniques used to characterize timing performance in telecommunications networks. Recently, a new measurement technique, Time Variance (TVAR) has gained acceptance in the North American (ANSI) standards body. TVAR was developed in concurrence with NIST to address certain inadequacies in the MTIE approach. The advantages and disadvantages of each of these approaches are described. Real measurement examples are presented to illustrate the critical issues in actual telecommunication applications. Finally, a new MTIE measurement is proposed (ZTIE) that complements TVAR. Together, TVAR and ZTIE provide a very good characterization of network timing. Author (revised)

TIMING IN PRIVATE DIGITAL TELECOMMUNICATION NETWORKS **c32**
J. E. Abate, C. D. Near, and M. S. Russo *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 327-336 (For primary document see N94-10963 01-70)
Avail: CASI HC A02/MF A04

For proper operation of today's large digital private networks, high quality synchronization must be achieved. A general telecommunication performance objective is to maintain long-term frequency accuracy of ten parts per trillion at all synchronous digital equipment in the network. Many times, however, this is not achieved in private networks. Low quality clocks, errored transmission facilities, and incorrectly designed synchronization plans are often cause for poor performance. It is shown that properly-designed private networks can operate with long term frequency averages between ten parts per trillion to ten parts per million. These performance levels can adversely impact customer applications. The most demanding applications are digital and voice band data, encrypted voice, facsimile, and video. In a typical private network operating at 0.01 parts per million, the user would experience reduced data throughput, dropped encrypted calls, unreadable facsimile pages, or interrupted video transmission dozens of times per day. The major contribution to poor private network synchronization performance is the interaction of Customer Premises Equipment (CPE) clocks and the network facilities used to distribute timing. The performance of typical CPE clocks and facilities, and their impact on customer applications, are discussed. CPE clock performance issues, along with private network architectural constraints, make synchronization planning extremely difficult. Planning is usually costly and requires specialized expertise. PERFORMANCE OF LOW-COST COMMERCIAL FIBER-OPTIC TRANSCEIVERS FOR REFERENCE FREQUENCY DISTRIBUTION
Richard Dragonette and Joseph J. Suter *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 343-356 (For primary document see N94-10963 01-70)
Avail: CASI HC A03/MF A04

Precision time and frequency reference signals were effectively disseminated using high-quality intricate fiber-optic distribution systems. The quality of signals distributed by such systems is excellent, but the cost of these systems makes them unavailable to many potential users. A study of signal quality maintained using inexpensive commercial transmitter/receiver pairs is undertaken. Seven different transmitter/receiver pairs obtained from four different manufacturers were thoroughly tested using a 5 MHz sinusoid derived from a precision, temperature controlled, crystal-controlled oscillator. The electrical signal output from each fiber-optic receiver was tested for spectral purity, single-sideband phase noise, and AM noise, and the results are tabulated and discussed without identification of the manufacturer or the equipment model number. ULTRASTABLE REFERENCE FREQUENCY DISTRIBUTION UTILIZING A FIBER OPTIC LINK
Malcolm Calhoun and Paul Kuhnle *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 357-364 (For primary document see N94-10963 01-70)
Avail: CASI HC A02/MF A04

The Frequency Standards Laboratory at the Jet Propulsion Laboratory (JPL) is responsible for the generation and distribution of ultra-stable reference frequency in NASA's Deep Space Network (DSN). Certain assemblies and components of the Radio Science and VLBI systems are located in the cones of tracking antennas hundreds of meters from the Frequency and Timing Subsystem's frequency standards. The very stringent requirements of these users challenge the performance of state-of-the-art frequency sources as well as the associated signal distribution system. The reference frequency distribution system described is designed around a low temperature coefficient of delay (TCD) optical fiber. On-site measurements of the fiber optic link alone indicate 100 MHz phase noise performance on the order of -120 dBc at 1 Hz from the carrier and Allan deviation on the order of parts in 10(exp 16) at 1000 seconds averaging time. The measured phase noise and stability of the link indicate that the performance characteristics of the hydrogen maser frequency standards are not degraded by the distribution system. Thus, optical fibers and electro-optic devices as distribution media appear to be a viable alternative to the classical coaxial cable distribution systems. Author (revised)

A WIDE-BAND FIBER OPTIC FREQUENCY DISTRIBUTION SYSTEM EMPLOYING THERMALLY CONTROLLED PHASE COMPENSATION
Dean Johnson (University of Western Michigan, Kalamazoo.), Malcolm Calhoun, Richard Sydnor, and George Lutes *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 365-374 (For primary document see N94-10963 01-70)
Avail: CASI HC A02/MF A04

An active wide-band fiber optic frequency distribution system employing a thermally controlled phase compensator to stabilize phase variations induced by environmental temperature changes is described. The distribution system utilizes bidirectional dual wavelength transmission to provide optical feedback of induced phase variations of 100 MHz signals propagating along the distribution cable. The phase compensation considered differs from earlier narrow-band phase compensation designs in that it uses a thermally controlled fiber delay coil rather than a VCO or phase modulation to compensate for induced phase variations. Two advantages of the wide-band system over earlier designs are (1) that it provides phase compensation for all transmitted frequencies, and (2) the compensation is applied after the optical interface rather than electronically ahead of it as in earlier schemes. Experimental results on the first prototype shows that the thermal stabilizer reduces phase variations and Allan deviation by a factor of forty over an equivalent uncompensated fiber optic distribution system. ESTIMATING THE INSTABILITIES OF N CLOCKS BY MEANS OF COMPARISON MEASUREMENTS
Amedeo Premoli and Patrizia Tavella (Instituto Elettrotecnico Nazionale, Galileo Ferraris, Turin, Italy.) *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 385-398 (For primary document see N94-10963 01-70)
Avail: CASI HC A03/MF A04

The estimation of individual instabilities of N clocks, compared by measuring the differences of their readings, is considered without assuming a priori any hypotheses on their uncorrelation. Instabilities of the N clocks are described by a complete (non-diagonal) N x N covariance matrix R. Only differences of clock readings are available in order to estimate R. Statistical processing of these data allows one to calculate the (N-1)x(N-l) covariance matrix S of the differences relative to the N-th(reference) clock. By analyzing the relationships tying R and S, several pieces of information can be inferred and, in particular, the conditions for the validity of the uncorrelation hypothesis are established. The estimation of R from S is not unique: in any case R must be positive definite. A theorem states that R is positive definite if and only if its determinant is positive. Nevertheless infinitely many acceptable choices of R still fulfill the condition of positive definiteness. This paper shows that, by increasing the number N of compared clocks, the amount of arbitrariness in estimating R is reduced. The analysis of some experimental data illustrates the capability of the method. Author (revised)

TIME SCALE ALGORITHMS FOR AN INHOMOGENEOUS GROUP OF ATOMIC CLOCKS
C. Jacques, J.-S. Boulanger, R. J. Douglas, D. Morris, S. Cundy, and H. F. Lam *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 399-412 (For primary document see N94-10963 01-70)
Avail: CASI HC A03/MF A04

Through the past 17 years, the time scale requirements at the National Research Council (NRC) have been met by the unsteered output of its primary laboratory cesium clocks, supplemented by hydrogen masers when short-term stability better than 2 x 10(exp -12)tau(sup -1/2) has been required. NRC now operates three primary laboratory cesium clocks, three hydrogen masers, and two commercial cesium clocks. NRC has been using ensemble averages for internal purposes for the past several years, and has a realtime algorithm operating on the outputs of its high-resolution (2 x 10(exp -13) s at 1 s) phase comparators. The slow frequency drift of the hydrogen masers has presented difficulties in incorporating their short-term stability into the ensemble average, while retaining the long-term stability of the laboratory cesium frequency standards. We report on this work on algorithms for an inhomogeneous ensemble of atomic clocks, and on our initial work on time scale algorithms that could incorporate frequency calibrations at NRC from the next generation of Zacharias fountain cesium frequency standards having frequency accuracies that might surpass 10(exp -15), or from single-trapped-ion frequency standards (Ba+, Sr+,...) with even higher potential accuracies. The requirements for redundancy in all the elements (including the algorithms) of an inhomogeneous ensemble that would give a robust real-time output of the algorithms are presented and discussed. Recently a new technique for characterizing the noise processes affecting oscillators was introduced. This technique minimizes the difference between the estimates of several different variances and their values as predicted by the standard power law model of noise. The method outlined makes two significant advancements: it uses exclusively time domain variances so that deterministic parameters such as linear frequency drift may be estimated, and it correctly fits the estimates using the chi-square distribution. These changes permit a more accurate fitting at long time intervals where there is the least information. This technique was applied to both simulated and real data with excellent results. SPACECRAFT SIGNAL SOURCES PORTABLE TEST SYSTEM c32
Albert Kirk, Paul Kuhnle, Richard Sydnor, William Diener, and David Stowers *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 427-438 (For primary document see N94-10963 01-70)
Avail: CASI HC A03/MF A04

There is a frequent need to measure the frequency stability and phase noise levels of very high performance signal sources that are required for certain spacecraft missions. These measurements need to be done at different locations as the spacecraft subsystems progress through the various stages of development, assembly, test, and integration. Allan Deviation and Phase Noise of high performance sources are generally measured by comparing the unit under test to a reference standard. Five basic requirements are associated with making these kind of measurements: (1) the reference standard performance needs to be equal or better than the unit under test; (2) the measurement system needs to accommodate odd, nonstandard measurement frequencies that can range from 4 MHz to 35 GHz; (3) warm-up frequency drift and aging can corrupt a measurement and must be dealt with; (4) test equipment generated noise must be understood and prevented from limiting the measurements; (5) test equipment noise performance must be verifiable in the field as needed. A portable measurement system that was built by JPL and used in the field is described. The methods of addressing the above requirements are outlined and some measurement noise floor values are given. This test set was recently used to measure state of the art crystal oscillator frequency standards on the TOPEX and MARS OBSERVER spacecraft during several stages of acceptance tests. THE LIMIT OF FREQUENCY ESTIMATION
Wei Guo *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 439-444 (For primary document see N94-10963 01-70)
Avail: CASI HC A01/MF A04

In phase and frequency measurements, the measured phase and frequency are not the true phase and frequency but the ones which are disturbed by noises, due to the effects of the noise processes. The effects of three noise processes, i.e., White PM, White FM, and Random Walk FM, on the estimations of phase and frequency is discussed. It is indicated that the properties of these two estimations are very different. In phase estimation, the error can be reduced by properly selecting suitable smoothing length NT and smaple interval T. But in frequency estimation, the error cannot be reduced arbitrarily by means of improving estimator or measurement equipment. The precision of frequency is limited by the intrinsic noises in the clock. Author (revised)

A NEW METHOD OF TIME DIFFERENCE MEASUREMENT: THE TIME DIFFERENCE METHOD BY DUAL PHASE COINCIDENCE POINTS DETECTION
Wei Zhou *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 445-450 (For primary document see N94-10963 01-70)
Avail: CASI HC A02/MF A04

In the high accurate measurement of periodic signals, the greatest common factor frequency and its characteristics have special functions. A method of time difference measurement - the time difference method by dual 'phase coincidence points' detection is described. This method utilizes the characteristics of the greatest common factor frequency to measure time or phase difference between periodic signals. It can suit a very wide frequency range. Measurement precision and potential accuracy of several picoseconds were demonstrated with this new method. The instrument based on this method is very simple, and the demand for the common oscillator is low. This method and instrument can be used widely. Author (revised)

CONFIDENCE OF THE THREE-POINT ESTIMATOR OF FREQUENCY DRIFT
Marc A. Weiss and Christine Hackman *In* NASA. Goddard Space Flight Center, The 24th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting Jun. 1993 p 451-460 (For primary document see N94-10963 01-70)
Avail: CASI HC A02/MF A04

It was shown that a three-point second difference estimator is nearly optimal for estimating frequency drift in many common atomic oscillators. A formula for the uncertainty of this estimate as a function of the integration time and of the Allan variance associated with this integration time is derived. Author (revised)

ESTIMATION OF THE DIRECT ACOUSTIC RADIATION FROM TURBULENT SPOTS USING BOUNDARY LAYER VELOCITY MEASUREMENTS Ph.D. Thesis
Michael H. Krane 1992 154 p
Avail: Univ. Microfilms Order No. DA9311669

To provide understanding of the acoustic source characteristics of the boundary layer transition region, unsteady velocity measurements of an isolated, artificially generated turbulent spot were made in a zero-pressure gradient laminar boundary layer. These measurements were performed in a water channel using a laser velocimeter and are used to describe the fluctuations of unsteady displacement thickness due to the passage of the turbulent spot. These fluctuations are related to the radiated noise through the Liepmann acoustic analogy. The velocity normal to the plate and the characteristic rise time, t(sub i), of the displacement thickness were calculated from the unsteady displacement thickness. Comparing the results at different streamwise stations shows that the rise time and displacement thickness fluctuation amplitude increase with distance from the generation point, while the peak amplitudes of the normal velocity increase early in the spot development, but level off. For all these parameters, the rate of spatial growth is highest in the stations closest to the turbulent spot generation point. Scaling analysis using the experimental results suggests that the sound radiated by the large-scale motion due to an isolated turbulent spot has a dipole character. Extrapolation to a natural transition zone indicates that the dipole source strength distribution peaks near the midpoint of the transition zone. Measurements of interacting turbulent spot pairs were carried out to test the limits of applicability of the isolated spot results to a natural transition zone. To the degree of interaction present in these experiments, the isolated spot growth was not significantly different from that found for the interacting spots. Dissert. Abstr.

PERPENDICULAR BLADE VORTEX INTERACTION AND ITS IMPLICATIONS FOR HELICOPTER NOISE PREDICTION: WAVE-NUMBER FREQUENCY SPECTRA IN A TRAILING VORTEX FOR BWI NOISE PREDICTION Final Technical Report, period ending 15 Aug. 1993
William J. Devenport and Stewart A. L. Glegg (Florida Atlantic Univ., Boca Raton.) Aug. 1993 367 p Original contains color illustrations

(NASA-CR-193623; NAS 1.26:193623) Avail: CASI HC A16/MF A03; 3 functional color pages

Perpendicular blade vortex interactions are a common occurrence in helicopter rotor flows. Under certain conditions they produce a substantial proportion of the acoustic noise. However, the mechanism of noise generation is not well understood. Specifically, turbulence associated with the trailing vortices shed from the blade tips appears insufficient to account for the noise generated. The hypothesis that the first perpendicular interaction experienced by a trailing vortex alters its turbulence structure in such a way as to increase the acoustic noise generated by subsequent interactions is examined. To investigate this hypothesis a two-part investigation was carried out. In the first part, experiments were performed to examine the behavior of a streamwise vortex as it passed over and downstream of a spanwise blade in incompressible flow. Blade vortex separations between +/- one eighth chord were studied for at a chord Reynolds number of 200,000. Three-component velocity and turbulence measurements were made in the flow from 4 chord lengths upstream to 15 chordlengths downstream of the blade using miniature 4-sensor hot wire probes. These measurements show that the interaction of the vortex with the blade and its wake causes the vortex core to loose circulation and diffuse much more rapidly than it otherwise would. Core radius increases and peak tangential velocity decreases with distance downstream of the blade. True turbulence levels within the core are much larger downstream than upstream of the blade. The net result is a much larger and more intense region of turbulent flow than that presented by the original vortex and thus, by implication, a greater potential for generating acoustic noise. In the second part, the turbulence measurements described above were used to derive the necessary inputs to a Blade Wake Interaction (BWI) noise prediction scheme. This resulted in significantly improved agreement between measurements and calculations of the BWI noise spectrum especially for the spectral peak at low frequencies, which previously was poorly predicted. BASIC EXPERIMENT ON AN ULTRASONIC METHOD OF LOCALIZATION
Yoshio Fujii, Shinji Inomata, Katsuo Suzuki, Tomoaki Suzudo, and Yoshikuni Shinohara Aug. 1992 70 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-754295; JAERI-M-92-112) Avail: Issuing Activity (Department of Energy (DOE))

The results of the basic experiment on ultrasonic method of localization of mobile robots working in very strong radiation environments in nuclear facilities or in a room filled with opaque medium such as dense smoke where video cameras cannot function are described. The basic characteristics of the ultrasonic sensors used, the outline of the system for sensor signal processing, and the parallel processing method for structured programs are also described. The results of the experiment show that it is possible to identify the location with sufficient accuracy by proper use of the ultrasonic sensors and of signal processing method. It is also shown that countermeasures must be taken to organize a precise and stable measurement system. The parallel processing method applied is effective when using synchronization for communication among multiple structured processes and can also be applied to other sensor signal processing systems. AN EXPERIMENTAL INVESTIGATION OF THE SOURCES OF PROPELLER NOISE DUE TO TURBULENCE INGESTION Ph.D. Thesis
Daniel Francis Scharpf 1993 287 p
Avail: Univ. Microfilms Order No. DA9311108

Experimental measurements were performed on a four-bladed, 10-inch diameter marine propeller operating in a new open-jet, anechoic wind tunnel. A significant portion of the work consisted of the design, construction, and calibration of the wind tunnel facility. The wind tunnel could be operated from 5-100 ft/s with open-jet lengths from 2-7 feet. When the wind tunnel was installed the majority of the chamber had a low-frequency cut-off of 150 Hz. The freestream velocity and propeller rotational speed were 33 ft/s and 3000 RPM, respectively. Turbulence was generated at the exit plane of the wind tunnel inlet by square-mesh grids composed of cylindrical rods which resulted in turbulence levels at the propeller location from 0.2-5.5 percent. Measurements included steady thrust and torque, detailed hot wire surveys of the incoming flow and propeller wake, and sound pressure levels detailing the acoustic spectra and directivity. Bicoherence measurements in the propeller wake showed high coherence between the blade passage harmonics and the broadband frequencies near the hub and tip regions of the blades which indicated that the wake interactions were primarily non-linear. Inflow turbulence reduced this coherence. The integrated broad-band sound pressure level increased by approximately 2 dB for every 1 percent increase in the turbulence. These increases were decomposed into smaller frequency bandwidths and related to the inflow turbulence spectrum. Dissert. Abstr.

CONTROL OF JET NOISE Final Report, 1 Feb. 1992 - 30 Jun. 1993
Stefan Schreck 1993 45 p Submitted for publication
(Grant NAG1-1096)
(NASA-CR-193612; NAS 1.26:193612) Avail: CASI HC A03/MF A01

This reports describes experiments conducted at the High-Speed Jet Facility at the University of Southern California on supersonic jets. The goal of the study was to develop methods for controlling the noise emitted from supersonic jets by passive and/or active means. Work by Seiner et al (1991) indicates that eddy Mach wave radiation is the dominant noise source in a heated high speed jet. Eddy Mach radiation is caused by turbulent eddies traveling at supersonic speed in the shear layer of the jet. The convection velocity of the eddies decays with increasing distance from the nozzle exit due to the mixing of the jet stream with the ambient fluid. Once the convection speed reaches subsonic velocities, eddy Mach wave radiation ceases. To control noise, a rapid decay of the convection velocity is desired. This may be accomplished by enhanced mixing in the jet. In this study, small aspect ratio rectangular jet nozzles were tested. A flapping mode was noticed in the jets. By amplifying screech components of the jets and destabilizing the jet columns with a collar device, the flapping mode was excited. The result was a rapid decay of the jet velocity. A reduction in eddy Mach radiation in rectangular supersonic jets may be achieved with this device. Author

This report documents work carried out in the Materials Research Laboratory of the Pennsylvania State University over the first year of a new ONR sponsored University Research Initiative (URI) entitled Materials for Adaptive Structural Acoustic Control. For this report the activities have been grouped under the following topic headings: (1) General Summary Papers; (2) Materials Studies; (3) Composite Sensors; (4) Actuator Studies; (5) Integration Issues; (6) Processing Studies; and (7) Thin Film Ferroelectrics. In material studies important advances have been made in the understanding of the evaluation of relaxor behavior in the PLZT's and of the order-disorder behavior in lead scandium tantalate:lead titanate solid solutions and of the Morphotropic Phase Boundary in this system. For both composite sensors and actuators, we have continued to explore and exploit the remarkable versatility of the flextensional moonie type structure. Finite element (FEA) calculations have given a clear picture of the lower order resonant modes and permitted the evaluation of various end cap metals, cap geometries, and load conditions. In actuator studies multilayer structures have been combined with flextensional moonie endcaps to yield high displacement (50 micrometers) compact structures. Electrically controlled shape memory has been demonstrated in lead zirconate stannate titanate compositions, and used for controlling a simple latching relay. DTIC

A crossed laser-negative ion beams apparatus, situated at Oak Ridge National Laboratory, has been used for energy and angle-resolved photoelectron spectroscopic measurements following photodetachment. In the current grant period, measurements of the cross sections for photodetaching an electron from the Li(-) ion were finished. Measurements of the sigma(B(-))/sigma(Li(-)) ratio, with a goal of determining photodetachment cross section for B(-), were started. An investigation of the photodetachment of the metastable ion Be(-) also began. Preliminary data on the electron affinity, asymmetry parameter and cross section associated with the photodetachment of Be(-) at a photon energy of 2.076 eV is reported. DOE

AN INTERCOMPARISON OF THE RADIUM MASS STANDARDS OF THE UK AND THE USSR: 2

S. A. Woods, P. Cross, P Christmas, E. A. Kholnova (All-Union Scientific Research Inst., Saint Petersburg, Russia.), M. F. Yudin (All-Union Scientific Research Inst., Saint Petersburg, Russia.), and E. S. Gubkin (All-Union Scientific Research Inst., Saint Petersburg, Russia.) Oct. 1992 12 p
(NPL-RSA(EXT)-34; ETN-93-93747) Copyright Avail: Issuing Activity (National Physical Laboratory, Teddington, Middlesex, TW11 OLW, England)

A comparison of national radium standards of the UK and the USSR as part of bilateral cooperation in the field of activity measurements is presented. The measurement methods for calorimetric and ionometric comparisons are described. Tables show: observed counting rates in the 1764 keV photopeak together with calculated source transmissions; analysis of individual uncertainty components arising in the determination of the radium content of X5; and calculated mean energy components. The results of all measurements, decay corrected to a common reference time of 1 Jan. 1989, are tabulated, and show that good agreement between the various methods of measurement employed in the intercomparison was achieved. TOP AND HIGGS MASSES IN A COMPOSITE BOSON MODEL

D. E. Kahana and S. H. Kahana Jan. 1993 5 p Presented at the Meeting of the Division of Particles and Fields of the American Physical Society, Batavia, IL, 10-14 Nov. 1992
(Contract DE-AC02-76CH-00016)
(DE93-010874; BNL-48605; CONF-921122-48) Avail: CASI HC A01/MF A01

Recently Nambu as well as Bardeen, Hill and Linden have suggested replacing the Higgs mechanism with a dynamical symmetry breaking generated by four fermion interactions of the top quark. In fact the model for replacing the scalar sector is that of Nambu and Jona-Lasinio (NJL) and one recovers the Higgs as a tt composite. Earlier authors have also treated vector mesons as composites within the NJL framework, with perhaps the earliest suggestion being that of Bjorken for a composite photon. Here we attempt to generate the entire electroweak interaction from a specific current-current, baryon number conserving form of the four fermion interaction. The W, Z and Higgs boson appear as coherent composites of all fermions, quarks and lepton, and not just of the top quark. The four fermion interaction is assumed to be valid at some high mass scale (mu), perhaps the low energy limit resulting by the elimination of non-fermionic degrees of freedom from a more basic theory. The cutoff (Lambda), necessary in the non-renormalizable NJL may be viewed then as the proper scale for this more basic theory. DOE

PRODUCTION OF STRANGE CLUSTERS IN RELATIVISTIC HEAVY ION COLLISIONS

C. B. Dover, A. J. Baltz, Yang Pang, T. J. Schlagel, and S. H. Kahana Feb. 1993 17 p Presented at the HIPAGS Meeting, Cambridge, MA, 14-17 Jan. 1993
(Contract DE-AC02-76CH-00016)
(DE93-010876; BNL-48594; CONF-930173-5) Avail: CASI HC A03/MF A01

We address a number of issues related to the production of strangeness in high energy heavy ion collisions, including the possibility that stable states of multi-strange hypersonic or quark matter might exist, and the prospects that such objects may be created and detected in the laboratory. We make use of events generated by the cascade code ARC to estimate the rapidity distribution dN/dy of strange clusters produced in Si+Au and Au+Au collisions at AGS energies. These calculations are performed in a simple coalescence model, which yields a consistent description of the strange cluster (d, He-3, H-3, He-4) production at these energies. If a doubly strange, weakly bound (Lambda)(Lambda) dibaryon exists, we find that it is produced rather copiously in Au+Au collisions, with dN/dy (approximately)0.1 at mid-rapidity. If one adds another non-strange or strange baryon to a cluster, the production rate decreases by roughly one or two orders of magnitude, respectively. For instance, we predict that the hypernucleus (Lambda)(Lambda)He-6 should have dN/dy (approximately)5 x 10(sup -6) for Au+Au central collisions. It should be possible to measure the successive (Lambda) yields p(pi(-)) weak decays of this object. We comment on the possibility that conventional multi-strange hypernuclei may serve as 'doorway states' for the production of stable configurations of strange quark matter, if such states exist. DOE

INTEGRATED CROSS SECTIONS FOR THE IONISATION OF ATOMIC HYDROGEN BY ELECTRON IMPACT

D. A. Konovalov and I. E. McCarthy May 1992 10 p
(DE93-610179; ESM-44) Avail: CASI HC A02/MF A01 (US Sales Only)

Distorted-wave Born approximation (DWBA) calculations are reported for singly-differential and total cross sections for the electron impact ionization for atomic hydrogen at 25, 40, 60, 100, 150, and 250 eV. The theory is compared with available experiments. At all the energies except 25 eV the theory predicts a lower singly-differential cross section for the low-energy side of the secondary-electron energies (less than 5 eV), compared to the only available absolute measurements of Shyn. The DWBA calculation is in good agreement with the experiment at 25 eV but only if e-e post-collision interaction is included in the theory in some way. DOE

CALCULATION OF THE TOTAL IONIZATION CROSS SECTION AND SPIN ASYMMETRY IN ELECTRON-HYDROGEN SCATTERING FROM THRESHOLD TO 500 eV

I. Bray and A. T. Stelbovics Jul. 1992 9 p
(DE93-610180; ESM-47) Avail: CASI HC A02/MF A01 (US Sales Only)

The total ionization cross section and spin asymmetry at projectile energies ranging from threshold to 500 eV for electron impact excitation of atomic hydrogen is presented. They are calculated using the convergent close-coupling formalism of Bray and Stelbovics. Both observables are found to be in complete quantitative agreement with measurements over almost the entire energy range. This is the only electron-atom scattering theory that is able to achieve this result to date. DOE

REPORT OF THE WORKSHOP ON LIGHT PARTICLE-INDUCED REACTIONS

1992 330 p Workshop held in Osaka, Japan, 5-7 Dec. 1991

(DE93-752300; RCNP-P-120; CONF-9112148) Avail: CASI HC A15/MF A03

The study meeting on light particle (mass number = 3 - 11) induced reaction was held for three days from 5-7 Dec. 1991 at the Research Center for Nuclear Physics, Osaka University. This book records the reports based on the lectures presented at the meeting. In the new facility of the RCNP, the experiment on the nuclear reaction using 400 MeV polarized protons and 200 MeV polarized deuterons is about to begin. When the acceleration of polarized He-3 beam which is being developed becomes feasible, by combining it with the high resolution spectrometer GRAND RAIDEN, it is expected that the unique, high accuracy research using the polarized He-3 having intermediate energy (540 MeV) becomes possible. At this time, by focusing attention to what new physics is developed by the nuclear reaction induced by the composite particles having the intermediate energy of mass number 3 - 11, this study meeting was planned and held. As the result, 29 lectures collected were to cover wide fields, and active discussion was carried out. DOE

SATELLITE STRUCTURE OF THE XENON VALENCE SHELL BY ELECTRON MOMENTUM SPECTROSCOPY

S. Braidwood, M. Brunger, and E. Weigold May 1992 25 p

(DE93-609993; ESM-43) Avail: CASI HC A03/MF A01 (US Sales Only)

Momentum distributions and spectroscopic factors are obtained in a high resolution electron momentum spectroscopy (EMS) study of xenon at 1000 eV. The shapes and relative magnitudes of the momentum profiles are in excellent agreement with distorted-wave impulse approximations using the target Dirac-Fock approximation. The DWDF approximation accurately describes the relative magnitudes of the 5p and 5s manifold cross sections as well as the shape of the 5s cross section. The use of nonrelativistic Hartree-Fock wavefunctions gives significantly poorer fits to the data. Spectroscopic factors for transitions belonging to the (sup 2)S(sup e)(sub 1/2),P(sup 0)(sub 1/2,3/2), and (sup 2)D(sup 3)(sub 3/2,5/2) manifolds are assigned up to a separation energy of 45 eV. The spectroscopic strength for the lowest 5s transition is 0.345 +/- 0.010 whereas that for the ground state 5p transition is 0.96 +/- 0.02. The 5s strength in the continuum above 33.1 eV is 0.115 +/- 0.025 and that for the 5p manifold is only 0.03 +/- 0.01. The first momentum profiles belong to excited (sup 2)P(sup 0) and (sup 2)D(sup e) manifolds are obtained. The latter, which must be entirely due to d-wave correlations in the xenon ground state, are in good agreement with DF 5d momentum profiles. Comparison is made with several many-body calculations and agreement with the latest relativistic calculation is very good. DOE

N94-10328# Flinders Univ., Adelaide (Australia). Electronic Structure of Materials Centre.

CONVERGENT CLOSE-COUPLING CALCULATIONS OF ELECTRON-HYDROGEN SCATTERING

Igor Bray and A. T. Stelbovics Apr. 1992 32 p

(DE93-610049; ESM-41) Avail: CASI HC A03/MF A01 (US Sales Only)

The convergence of the close-coupling formalism is studied by expanding the target states in an orthogonal L(sup 2) Laguerre basis. The theory is without approximation and convergence is established by simply increasing the basis size. The convergent elastic 2s and 2p differential cross sections, spin asymmetries, and angular correlation parameters for the 2p excitation at 35, 54.4, and 100 eV are calculated. Integrated and total cross sections as well as T-matrix elements for the first five partial waves are also given. DOE

N94-10329# Flinders Univ., Adelaide (Australia). Electronic Structure of Materials Centre.

CALCULATION OF SPIN-DEPENDENT OBSERVABLES IN ELECTRON-SODIUM SCATTERING USING THE COUPLED-CHANNEL OPTICAL METHOD

Igor Bray Apr. 1992 8 p

(DE93-610050; ESM-42) Avail: CASI HC A02/MF A01 (US Sales Only)

The calculations of the 3(sup 2)S and 3(sup 2)P spin asymmetries and the angular momentum for singlet and triplet scattering for projectile energies of 10 and 20 eV is presented. Together these observables give a most stringent test of any electron-atom scattering theory. An excellent agreement was found between the results of the coupled-channel optical method and experiment, which for the spin asymmetries can only be obtained by a good description of the couplings between the lower-lying target states and the target continuum. DOE

N94-10330# Flinders Univ., Adelaide (Australia). Electronic Structure of Materials Centre.

DISTORTED-WAVE CALCULATION OF He(e,2e) INCLUDING CORE-EXCHANGE

D. A. Konovalov and I. E. McCarthy Apr. 1992 14 p

(DE93-610072; ESM-40) Avail: CASI HC A03/MF A01 (US Sales Only)

Distorted-wave Born approximation (DWBA) calculations are reported for coplanar symmetric ionization of helium at energies of 100 and 200 eV. The best possible one-configuration incident distorted wave functions together with the capture scattering were used to produce a better agreement with absolute measurements at 100 eV compared with the previous DWBA calculations. However, the discrepancy between experiment and theory at 200 eV for large angles was not resolved by these modifications. Moreover capture scattering was found negligible at 28.6 to 200 eV. Similar DWBA calculations for hydrogen close to the threshold are also reported. Very good agreement with experiment was found at 17.6 eV. DOE

SPIN-DEPENDENT OBSERVABLES IN ELECTRON-SODIUM SCATTERING CALCULATED USING THE COUPLED-CHANNEL OPTICAL METHOD

I. Bray and I. E. McCarthy Jun. 1992 22 p

(DE93-610073; ESM-45) Avail: CASI HC A03/MF A01 (US Sales Only)

The calculations of 3(sup 2)S-3(sup 2)S and 3(sup 2)S-3(sup 2)P electron-sodium scattering at 1 to 40 eV is presented. An excellent agreement with measurements of the spin asymmetries and P'/P for both channels, and L the angular momentum for singlet, triplet, and summed spin states at all energies was found. This may only be achieved at energies above the ionization threshold by including the coupling of the low-lying target discrete states to the target continuum. DOE

ELECTRON MOMENTUM SPECTROSCOPY OF ATOMS, MOLECULES AND SOLIDS

E. Weigold Jan. 1992 16 p

(DE93-610148; ESM-38) Avail: CASI HC A03/MF A01 (US Sales Only)

Electron Momentum Spectroscopy (EMS) is the application of the (e,2e) technique to obtain detailed information on the dynamic structure of atoms, molecules, and condensed matter. The ability of EMS to provide wavefunction mapping, in terms of the independent particle representation of a many body system in momentum space, is discussed for valence electrons. The quantitative measurement of correlation effects in both the initial and final electron states is demonstrated. Correlations can significantly change the momentum density distribution, as well as giving rise to transitions forbidden in the independent particle approximation. The case of argon is discussed in some detail since both initial state correlations (d-wave correlations) and final state correlations (mainly in the 3s(sup -1) manifold) are present. The influence of relativistic effects in outer valence momentum densities is demonstrated for Xe and Pb. The importance of correlations in the outer valence orbitals of some molecules is discussed with particular reference to H2O. The first (e,2e) results on an excited target and also an oriented target are discussed, as are some recent high resolution measurements on amorphous carbon. DOE

RECENT ADVANCES IN ELECTRON MOMENTUM SPECTROSCOPY

E. Weigold Mar. 1992 36 p

(DE93-610149; ESM-39) Avail: CASI HC A03/MF A01 (US Sales Only)

The flexibility of the (e,2e) technique or electron momentum spectroscopy in obtaining information on the electronic structure of atoms, molecules, and solids is demonstrated. High resolution electron momentum spectroscopy measurements for argon including the first measurements of momentum profiles belonging to the (sup 2)p(sup 0) and (sup 2)D(sup e) manifolds are used to demonstrate the technique for atomic targets. The d-wave transitions in argon are entirely due to initial state correlations. The first (e,2e) measurements on an excited target and also on an oriented target are also discussed. Sodium atoms are pumped to the m(sub l) = +1 state of the excited 3p state by (sigma)(sup +) light from a laser. The (e,2e) measurements on this excited state are in excellent agreement with the momentum density given by the 3p (m(sub l) = 1) Hartree-Fock wavefunction. The recent measurements of the valence electron momentum distributions for ethane as well as some earlier results for water are used as an example of the application of EMS to the study of molecules. The application of the EMS technique to measure spectral momentum densities in condensed matter targets is demonstrated by some recent results on amorphous carbon. DOE

THE EFFECT OF A SCALAR BOSON COUPLED TO NEUTRINOS ON THE BEHAVIOR OF THE TRITIUM BETA DECAY SPECTRUM NEAR THE END POINT

G. J. Stephenson, Jr. 1993 10 p Presented at the 13th Moriond Workshop on Perspectives in Neutrinos, Atomic Physics, and Gravitation, Villars-sur-Ollon, 30 Jan. - 6 Feb. 1993

(Contract W-7405-eng-36)

(DE93-012655; LA-UR-93-1243; CONF-930187-2) Avail: CASI HC A02/MF A01

Some consequences of a very light scalar boson coupled only to neutrinos are discussed. In particular, I argue that it is possible to sketch scenarios for the evolution of the Universe in which neutrinos cluster to a local density of approximately 10(exp 16) /cc, that such clusters would be attracted to matter gravitationally, and that the existence of such a neutrino density in the solar system provides an alternative to m(-)(sub ve)(sup 2) less than 0 in fitting tritium beta decay. DOE

ON PARITY CONSERVATION AND THE QUESTION OF THE MISSING, RIGHT-HANDED NEUTRINO

A. O. Barut and G. Ziino (Palermo Univ., Italy.) Sep. 1992 19 p

(DE93-613092; IC-92/279) Avail: CASI HC A03/MF A01 (US Sales Only)

The neutrino problem is set anew in the light of a reformulation of the Dirac field theory that provides a natural account for the effect commonly interpreted as 'P-violation', and restores P-mirror symmetry. A two-component (left-handed) neutrino field is automatically derived, whose P-mirror image does not correspond to a 'missing' particle but is the (right-handed) antineutrino field. DOE

N94-10502 International Centre for Theoretical Physics, Trieste (Italy).

MONTE CARLO SIMULATIONS OF A TWO-DIMENSIONAL HARD DIMER SYSTEM

K. W. Wojciechowski, A. C. Branka (Polish Academy of Sciences, Poznan.), and D. Frenkel (FOM-Inst. voor Atoom- en Molecuulfysica, Amsterdam, Netherlands.) Sep. 1992 37 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(DE93-613535; IC-92/278) Avail: CASI HC A03 (US Sales Only)

Monte Carlo simulations of a system of two-dimensional hard, homonuclear dimers are reported. The equation-of-state, structural and orientational properties, and the free energy were computed for the fluid phase and several crystalline and non-crystalline (non-periodic) solid structures. The differences in the Gibbs free energy between the various solid structures were found not to exceed 0.1k(sub B)T per particle. This is much less than the contribution to the entropy per particle due to degeneracy of the 'ground state' of the non-periodic solid which amounts to 0.857k(sub B)T. Hence, the thermodynamically stable solid structure of the system corresponds to a set of non-periodic arrangements of the molecular centers of mass and orientations. The coexistence pressure of the non-periodic solid and fluid is determined; it is located within the observed narrow hysteresis region. It is shown that structures of the crystalline solids are well approximated by a simple lattice model. DOE

N94-10503 International Centre for Theoretical Physics, Trieste (Italy).

STRUCTURE OF S - P BONDED METAL CLUSTERS WITH 8, 20 AND 40 VALENCE ELECTRONS

V. Kumar Oct. 1992 9 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(DE93-613643; IC-92/313) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

From studies on some clusters of metals and semiconductors, there appear some similarities in the structure of clusters with a given number of atoms and having the number of valence electrons corresponding to a shell closing. Results of the atomic and electronic structure of a few other clusters with 20 and 40 valence electrons, namely Sb(sub 4), Sn(sub 5) and Sb(sub 8) using the density functional molecular dynamics method are presented. It is suggested that the similarities in the structure and deviation from them may help to understand bonding characteristics in clusters and its evolution to bulk behavior. Our results on Sb(sub 8) cluster are preliminary but indicate that above room temperature its structure is two weakly interacting tetrahedra which is in general agreement with the observation of predominently antimony tetramers at T greater than 300 K. CROSSING-ODD SPIN EFFECTS IN THE DIPOLE MODEL OF HADRON SCATTERING
S. V. Akkelin and E. S. Martynov 1992 19 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-617692; ITP-92-11) Avail: CASI HC A03 (US Sales Only)

The spin amplitudes of the nucleon-nucleon and the meson-nucleon scattering at high energies and the bounded transferred momenta are calculated within the dipole pomeron model. In the case of non-degenerate input pomeron and odderon, the polarizations in proton-proton and proton-antiproton are shown to be opposite in sign and equal in value. In the meson-nucleon interactions, the polarization oscillates without changing its sign, the oscillation amplitude is then independent of energy in charge exchange process, and in the elastic scattering it gets decreased slowly. DOE

N94-10552 Academy of Sciences of the Ukraine, Kiev. Inst. Teoreticheskoj Fiziki.
MODEL FOR THE POMERON

ELECTRON RUNAWAY IN RF DISCHARGES
F. F. Chen Oct. 1992 26 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-771407; PSC-25) Avail: CASI HC A03

The critical electric field is computed as a function of pressure and starting energy for electrons to runaway to high energies in moderate pressure discharges. The runaway conditions depend critically on the shape of the elastic cross section vs. energy curve. Computations are made for H, H2, and He gases, and it is shown that runaway occurs much more readily in atomic hydrogen than in the other gases. The values of the runaway fields are larger than would normally occur in dc discharges, where large voltages would lead to arc formation. However, in rf discharges such electric fields can be sustained over times long compared to electron transit times but short compared to ion transit times. DOE

POSSIBILITY OF A CROSSED-BEAM EXPERIMENT INVOLVING SLOW-NEUTRON CAPTURE BY UNSTABLE NUCLEI RAPID-PROCESS-TRON
T. Yamazaki, I. Katayama, and Y. Uwamino Jul. 1992 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-754288; INS-940) Avail: Issuing Activity (Department of Energy (DOE))

The possibility of a crossed beam facility of slow neutrons crossed with unstable nuclei is examined in connection with the Japanese Hadron Project. With a pulsed proton beam of 50 Hz repetition with a 100 micro-Amp average beam current, one obtains a spallation neutron source of 2.4(10)(exp 8) thermal neutrons/cu cm/spill over a 60 cm length with a 3 msec average duration time by using a D2O moderator. By confining radioactive nuclei of 10(exp 9) ions in a beam circulation ring of 0.3 MHz revolution frequency, so that they pass through the neutron source, one obtains a collision luminosity of 3.9(10)(exp 24)/sq cm/s. A new research domain aimed at studying rapid processes in nuclear genetics will be created. DOE

(DE93-012740; LA-UR-93-1519; CONF-9305177-2) Avail: CASI HC A03

The General Structure Analysis System, GSAS, has recently been modified to include magnetic neutron-scattering cross-sections. Low-temperature diffraction data have been taken on the hexagonal noncollinear antiferromagnet UPdSn on both the HIPD and the NPD powder diffractometers at LANSCE. The low-resolution data reveal that the magnetic structure has orthorhombic symmetry (magnetic space group P(sub c)112(sub 1)) between 25K and 40K, and monoclinic symmetry (magnetic space group P(sub c)l12(sub 1)) below 25K. The high-resolution data reveal that there are structural distortions with corresponding symmetry changes in each of these phases, to give chemical space groups Cmc2(sub 1) and P2(sub 1) respectively, while the paramagnetic phase above 40K has space group P6(sub 3)mc. Using GSAS, we have refined data sets from both diffractometers simultaneously, including both magnetic and structural cross-sections. Magnetoelastic coefficients for the distortions have been extracted and we have determined the sip of the coupling between the structural monoclinicity and the magnetic monoclinicity. The magnetic results from Rietveld refinement are in good agreement with model fitting to the integrated intensities of seven independent magnetic reflections and these, in turn, agree with measurements made on the same sample using the constant-wavelength reactor technique. Our results therefore validate, to some level, both the technique of using spallation sources for complicated magnetic structures and the specifics of the GSAS Rietveld code. DOE

STRANGE MESON SPECTROSCOPY IN K(OMEGA) AND K(PHI) AT 11 GeV/c AND CHERENKOV RING IMAGING AT SLD Ph.D. Thesis
Youngjoon Kwon Jan. 1993 286 p
(Contract DE-AC03-76SF-00515)
(DE93-013593; SU-SLAC-409) Avail: CASI HC A13/MF A03

This thesis consists of two independent parts: development of a Cherenkov Ring Imaging Detector (CRID) system; and analysis of high-statistics data of strange meson reactions from the LASS spectrometer. The CRID system is devoted to charged particle identification in the SLAC Large Detector (SLD) to study e(+)e(-) collisions at radical s = m(sub Z(exp 0)). By measuring the angles of emission of the Cherenkov photons inside liquid and gaseous radiators, pi/K/p separation will be achieved up to approximately 30 GeV/c. The signals from CRID are read in three coordinates, one of which is measured by charge-division technique. To obtain an approximately 1% spatial resolution in the charge-division, low-noise CRID preamplifier prototypes were developed and tested resulting in less than 1000 electrons noise for an average photoelectron signal with 2(10)(exp 5) gain. To help ensure the long-term stability of CRID operation at high efficiency, a comprehensive monitoring and control system was developed. Results from the partial wave analysis of strange meson final states in the reactions K(-)p yields K(-)(omega)p and K(-)p yields (K-bar)(exp 0)(phi)n are presented. The analyses are based on data from a 4.1 event/nb exposure of the LASS spectrometer in K(-)p interactions at 11 GeV/c. The data sample of K(-)(omega)p final state contains approximately 10(exp 5) events. From the partial wave analysis, resonance structures of J(exp P) = 2(-), 3(-), and 2(+) amplitudes are observed in the K(omega) system. The analysis of 2(-) amplitudes provides an evidence for two strange meson states in the mass region around 1.75 GeV/sq c. The appropriate branching fractions are calculated and compared with the SU(3) predictions. The partial wave analysis of (K-bar)(exp 0)(phi) system favors J(exp P) = 1(-) and 2(+) states in the 1.9-2.0 GeV/sq c region. DOE

ATOMIC STRUCTURES AND COMPOSITIONS OF INTERNAL INTERFACES
D. N. Seidman and K. L. Merkle (Argonne National Lab., IL.) 10 May 1993 10 p
(Contract DE-FG02-89ER-45403)
(DE93-014840; DOE/ER-45403/4) Avail: CASI HC A02/MF A01

This research program addresses fundamental questions concerning the relations between atomic structures and compositions of homophase and heterophase interfaces. Metal/ceramic heterophase interfaces are created via the process of internal oxidation of metallic alloys. The interfaces are studied via a combination of conventional transmission electron microscopy, high resolution electron microscopy, field-ion microscopy, and atom probe microscopy. The latter technique is employed to chemically sequence the interfacial region, and to show that the terminating (222) plane of MgO and CdO consists solely of oxygen atoms for the Cu/MgO (111) and Ag/CdO (111) heterophase interfaces, respectively; this is achieved with no deconvolution of the experimental data. The evolution of metal/ceramic heterophase interfaces is studied by following the process of internal oxidation on an atomic scale from its very earliest stages. It is demonstrated that, during the early stages of internal oxidation, metal atom clusters as well as hypo- and hyperstoichiometric metal-oxygen clusters are present. Solute-atom segregation to grain boundaries is studied in binary metal alloys employing the free energy simulations and the overlapping distribution Monte Carlo methodologies for dilute Pt(Au), Cu(Ni) and Pd(Ni) alloys for both twist and tilt boundaries. (DE93-011742; CONF-9203159-9) Avail: CASI HC A02

Experimental results on the production of hadron jets in photon-photon interactions at PETRA and PEP are reviewed with special emphasis on the recent results from the TPC/2(gamma) experiment at PEP. All results have been compared with the predictions of Vector Dominance and Quark Parton Models and the experiments all find excess jet production at low Q(sup 2) and intermediate transverse momentum which cannot be explained on the basis of the simple VDM + QPM models. THE MULTIPLICITY SPECTRA OF THE (169)Tm(n, GAMMA) REACTION [SPEKTRY MNOZHESTVENNOSTI REAKSII 169TM(N, GAMMA)]
Y. G. Shchepkin, E. A. Pavlenko, and T. A. Senchenko et al 1991 13 p In RUSSIAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-617733; KIYal-91-41) Avail: CASI HC A03 (US Sales Only)

The multiplicity spectra of the (169)Tm(n,gamma) reaction for neutron energy 2 keV with different thickness of shield from (169)Tm samples were researched. The multiplicity spectrum correlation with shield thickness was not discovered but the difference between spectra for neutron energy 2 keV and thermal neutrons is observed. This difference can be related with dependence of multiplicity spectra from the spin of compound nucleus. The multiplicity spectrometry method is proposed to use for the separation of capture average cross section on components with different spin. DOE

The matrix method for description of the polarization components for ions moving through different electromagnetic systems: dipole magnets, cycle accelerators, quadrupole lenses, solenoids, wine filters, and electrostatic mirrors is developed in the paper. The expressions for elements of the transportation matrixes for the above-mentioned systems taking account of the projective trajectories are obtained. The program, TRANSPIN, for calculation of the beam polarization components after motion by ions of arbitrary number of electromagnetic elements along any possible trajectory is presented. The calculation results made for some of transportation lines for the isochronous cyclotron U-240 are discussed (trajectories for the ion motion were calculated by CERN-program TRANSPORT). The conditions for decrease of the polarization component dispersion because of difference between trajectories of the particles motion are also defined. DOE

THE INTRA-ATOMIC MOTION OF BOUND ELECTRONS AS A POSSIBLE SOURCE OF A SYSTEMATIC ERROR IN ELECTRON BEAM POLARIZATION MEASUREMENTS BY MEANS OF A MOELLER POLARIMETER
L. G. Levchuk 1992 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-620984; KFTI-92-32) Avail: CASI HC A03 (US Sales Only)

The role of the motion of electrons bound in target atoms in electron beam polarization measurements by means of a Moeller polarimeter is discussed. It is shown that this effect can result in an essential overestimate of the value being measured, which exceeds considerably the error of the target polarization determination, and therefore, it should be taken into account in the development of polarimeters. Some recommendations are given to eliminate this systematic error. DOE

WAVE GENERATION BY CONTAMINANT IONS Report, 1 Oct. 1992 - 30 Jun. 1993

N. Singh 1993 5 p
(Grant NAG3-1371)
(NASA-CR-193558; NAS 1.26:193558) Avail: CASI HC A01/MF A01

Investigations dealing with the generation of waves by contaminant ions are reported. The studies included the properties of the velocity distribution function of such ions. It was found that it takes about one ion-cyclotron period for the distribution function to transform from a beam to a ring distribution. A linear instability analysis was performed to examine the possibility of wave excitation by an ion beam streaming perpendicular to the ambient magnetic field in an ionospheric type of plasma. A simulation code was developed to study the nonlinear behavior of the waves excited by beam and ring types of ion distributions. The code treats both electrons and ions as particles kinetically to also factor in the possible involvement of lower-hybrid waves. CASI

THE SEARCHLIGHT PROBLEM FOR NEUTRONS IN A SEMI-INFINITE MEDIUM
B. D. Ganapol (Arizona Univ., Tucson.), D. W. Nigg, S. N. Jahshan, and C. A. Wemple 1993 11 p Presented at the International Topical Meeting on Mathematical Methods and Supercomputing in Nuclear Applications (M/C+SNA 1993), Karlsruhe, Germany, 19-23 Apr. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC07-76ID-01570)
(DE93-010796; EGG-M-92469; CONF-930404-14) Avail: CASI HC A03

The solution of the Search Light Problem for monoenergetic neutrons in a semi-infinite medium with isotropic scattering illuminated at the free surface is obtained by several methods at various planes within the medium. The sources considered are a normally-incident pencil beam and an isotropic point source. The analytic solution is effected by a recently developed numerical inversion technique applied to the Fourier-Bessel transform. This transform inversion results from the solution method of Rybicki, where the two-dimensional problem is solved by casting it as a variant of a one-dimensional problem. The numerical inversion process results in a highly accurate solution. Comparisons of the analytic solution with results from Monte Carlo (MCNP) and discrete ordinates transport (DORT) codes show excellent agreement. These comparisons, which are free of any associated data or cross section set dependencies, provide significant evidence of the proper operation of both the transport codes tested. DOE

EXPERIMENTS IN ULTRACOLD COLLISIONS
P. L. Gould 1992 4 p
(Contract DE-FG02-92ER-14263)
(DE93-012110; DOE/ER-14263/1) Avail: CASI HC A01/MF A01

Conditions in an ultracold magneto-optical laser trap were studied; the trap is being used to investigate collisions of Rb-85 and Rb-87 atoms at temperatures below 1 mK. The ballistic time-of-flight method was used to determine the temperature. It was found that the temperature increases monotonically with laser intensity; this means that the temperature dependence of various collisional processes can probably be measured. The trap size was found to be independent of laser intensity, except at the lowest intensities. DOE

The conditions are found under which solitons can be created and annihilated in nonlinear integrable systems (modified Korteweg-de Vries equation with a self-consistent source, sine-Gordon equation with a self-consistent source, etc.). The eigenvalue of the discrete spectrum of the corresponding linear Dirac operator turns out to depend on time and disappearance of any of the eigenvalues and leads to annihilation of the corresponding soliton. On the contrary, appearance in the discrete spectrum of a new eigenvalue leads to creation of an additional soliton corresponding to this eigenvalue. DOE

DEVELOPMENT OF DETERMINISTIC TRANSPORT METHODS FOR LOW ENERGY NEUTRONS FOR SHIELDING IN SPACE Final Report
Barry Ganapol 7 Sep. 1993 234 p
(Grant NAG1-1041)
(NASA-CR-194172; NAS 1.26:194172) Avail: CASI HC A11/MF A03

Transport of low energy neutrons associated with the galactic cosmic ray cascade is analyzed in this dissertation. A benchmark quality analytical algorithm is demonstrated for use with BRYNTRN, a computer program written by the High Energy Physics Division of NASA Langley Research Center, which is used to design and analyze shielding against the radiation created by the cascade. BRYNTRN uses numerical methods to solve the integral transport equations for baryons with the straight-ahead approximation, and numerical and empirical methods to generate the interaction probabilities. The straight-ahead approximation is adequate for charged particles, but not for neutrons. As NASA Langley improves BRYNTRN to include low energy neutrons, a benchmark quality solution is needed for comparison. The neutron transport algorithm demonstrated in this dissertation uses the closed-form Green's function solution to the galactic cosmic ray cascade transport equations to generate a source of neutrons. A basis function expansion for finite heterogeneous and semi-infinite homogeneous slabs with multiple energy groups and isotropic scattering is used to generate neutron fluxes resulting from the cascade. This method, called the FN method, is used to solve the neutral particle linear Boltzmann transport equation. As a demonstration of the algorithm coded in the programs MGSLAB and MGSEMI, neutron and ion fluxes are shown for a beam of fluorine ions at 1000 MeV per nucleon incident on semi-infinite and finite aluminum slabs. Also, to demonstrate that the shielding effectiveness against the radiation from the galactic cosmic ray cascade is not directly proportional to shield thickness, a graph of transmitted total neutron scalar flux versus slab thickness is shown. A simple model based on the nuclear liquid drop assumption is used to generate cross sections for the galactic cosmic ray cascade. The ENDF/B V database is used to generate the total and scattering cross sections for neutrons in aluminum. As an external verification, the results from MGSLAB and MGSEMI were compared to ANISN/PC, a routinely used neutron transport code, showing excellent agreement. In an application to an aluminum shield, the FN method seems to generate reasonable results. Author (revised)

A NEW DECOMPOSITION STRATEGY FOR PARALLEL BONDED MOLECULAR DYNAMICS
S. Plimpton, B. Hendrickson, and G. Heffelfinger 1992 11 p Presented at the 6th Society for Industrial and Applied Mathematics Conference on Parallel Processing for Scientific Computing, Norfolk, VA, 21-24 Mar. 1993
(Contract DE-AC04-76DP-00789)
(DE93-009839; SAND-92-0259C; CONF-930331-8) Avail: CASI HC A03/MF A01

A method is described for parallelizing molecular dynamics (MD) simulations by block-decomposing the matrix of bonded and non-bonded force computations. It is particularly useful for organic simulations (polymers, proteins) because unlike spatial-decomposition methods, it requires no geometric information about the simulation domain. Because its communication cost scales as N/(radical)P rather than N as in the all-to-all broadcast or ring-exchange techniques commonly used in this type of MD simulation, larger numbers of processors can be used effectively, yielding greater parallel speed-ups. ELECTRONIC EXCITATION OF GROUND STATE ATOMS BY COLLISION WITH HEAVY GAS PARTICLES Final Report, Jun. 1992 - Jun. 1993
C. Frederick Hansen Jun. 1993 20 p
(Grant NAG1-1427)
(NASA-CR-193364; NAS 1.26:193364) Avail: CASI HC A03/MF A01

Most of the important chemical reactions which occur in the very high temperature air produced around space vehicles as they enter the atmosphere were investigated both experimentally and theoretically, to some extent at least. One remaining reaction about which little is known, and which could be quite important at the extremely high temperatures that will be produced by the class of space vehicles now contemplated - such as the AOTV - is the excitation of bound electron states due to collisions between heavy gas particles. Rates of electronic excitation due to free electron collisions are known to be very rapid, but because these collisions quickly equilibrate the free and bound electron energy, the approach to full equilibrium with the heavy particle kinetic energy will depend primarily on the much slower process of bound electron excitation in heavy particle collisions and the subsequent rapid transfer to free electron energy. This may be the dominant mechanism leading to full equilibrium in the gas once the dissociation process has depleted the molecular states so the transfer between molecular vibrational energy and free electron energy is no longer available as a channel for equilibration of free electron and heavy particle kinetic energies. Two mechanisms seem probable in electronic excitation by heavy particle impact. One of these is the collision excitation and deexcitation of higher electronic states which are Rydberg like. A report, entitled 'Semi-Classical Theory of Electronic Excitation Rates', was submitted previously. This presented analytic expressions for the transition probabilities, assuming that the interaction potential is an exponential repulsion with a perturbation ripple due to the dipole-induced dipole effect in the case of neutral-neutral collisions, and to the ion-dipole interaction in the case of ion-neutral collisions. However the above may be, there is little doubt that excitation of ground state species by collision occurs at the point where the initial and final potentials cross, or at least come very close. Therefore, this mechanism would be applicable to the case where a gas is initially at very low temperature suddenly subjected to high energy heavy particle bombardment. This situation would model the measurement of excitation cross section by molecular beam techniques, for example. The purpose is to report values of cross sections and rate coefficients for collision excitation of ground state atoms estimated with the Landau-Zener transition theory and to compare results with measurement of excitation cross sections for a beam of Hydrogen atoms impacting Argon atom targets. Some very dubious approximations are used, and the comparison with measurement is found less than ideal, but results are at least consistent within order of magnitude. The same model is then applied to the case of N-N atom collisions, even though the approximations then become even more doubtful. Still the rate coefficients obtained are at least plausible in both magnitude and functional form, and as far as I am aware these are the only estimates available for such rate coefficients. PARALLEL MOLECULAR DYNAMICS WITH THE EMBEDDED ATOM METHOD
S. J. Plimpton and B. A. Hendrickson 1993 7 p Presented at the 16th Material Research Society International Symposium on the Scientific Basis for Nuclear Waste Management Fall Meeting, Boston, MA, 30 Nov. - 5 Dec. 1992
(Contract DE-AC04-76DP-00789)
(DE93-010683; SAND-93-0260C; CONF-921101-110) Avail: CASI HC A02/MF A01

Parallel computing offers new capabilities for using molecular dynamics (MD) to simulate larger numbers of atoms and longer time scales. In this paper we discuss two methods we have used to implement the embedded atom method (EAM) formalism for molecular dynamics on multiple-instruction/multiple-data (MIMD) parallel computers. The first method (atom-decomposition) is simple and suitable for small numbers of atoms. The second method (force-decomposition) is new and is particularly appropriate for the EAM because all the computations are between pairs of atoms. Both methods have the advantage of not requiring any geometric information about the physical domain being simulated. We present timing results for the two parallel methods on a benchmark EAM problem and briefly indicate how the methods can be used in other kinds of materials MD simulations. DOE

DEVELOPMENT OF MICROSTRIP GAS CHAMBERS WITH MULTI-CHIP TECHNOLOGY
T. Nagae, T. Tanimori, T. Kobayashi, and T. Miyagi Mar. 1992 15 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-753169; INS-919) Avail: CASI HC A03

The Microstrip Gas Chamber (MSGC) was developed by using Multi-Chip technology which supports high-density assembly of bare LSI chips on a silicon wafer. Our MSGC was operated steadily with approximately 10(exp 3) gain more than one week. An energy resolution of 15% for 5.9 keV X-ray of Fe-55 source was obtained. With a very thin polyimide substrate of 16 microns thickness, two interesting phenomena were observed; one was a strong dependence of gains on back plane potential, and the other was little time variation of gains. It was also found that a guard mask of a thin polyimide layer on the cathode edge reduced incidental electrical discharges between anode and cathode strips. DOE

CONCEPTUAL DESIGN REPORT FOR THE SDC BARREL AND INTERMEDIATE MUON DETECTORS BASED ON A JET-TYPE DRIFT CHAMBER
Y. Arai, Y. Funahashi, and Y. Higashi Apr. 1992 241 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-753173; KEK-92-1) Avail: CASI HC A11

A jet-type drift chamber for the barrel and intermediate muon detectors of SDC is proposed. The chamber system consists of large multiwire drift chambers having a simple box-type frame structure: 2.5 x 0.4 m(sup 2) in cross section and maximum 9 m in length. A chamber module consists of double layers of small jet cells. The drift cell is composed of a wire plane, including 3 sense wires, and cathode plates parallel to the wire plane. The two layers in a chamber are staggered to each other by half a cell width. The jet cell is tilted such that its principle axis points to the interaction point. Such an arrangement, together with a constant drift velocity of the jet cell, allows us to design a simple and powerful trigger system for high momentum muons utilizing a drift time sum between a pair of staggered cells. The multi-hit capability will be helpful to distinguish high momentum muon tracks from associated electromagnetic debris as was demonstrated by the Fermilab beam test T816. The maximum drift time fulfills the SDC requirement. A preliminary FEM analysis of the chamber module verified the excellent structural stiffness. It makes the support structure and the alignment system relatively simple. These features will reduce the total cost as well as ensure a good performance of the chamber system. DOE

A method of calculation of forward scattering amplitude for fermions and scalar bosons with exchanging of scalar particle is suggested. The Bethe-Salpeter ladder equation for the imaginary part of the amplitude is constructed and a solution in Regge asymptotical form is found and the corrections to the amplitude due to the exit from mass shell are calculated. A MOLECULAR DYNAMICS SIMULATION CODE ISIS
Shaw Kambayashi (Japan Atomic Energy Research Inst., Tokai.) Jun. 1992 51 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-753187; JAERI-M-92-080) Avail: CASI HC A04

Computer simulation based on the molecular dynamics (MD) method has become an important tool complementary to experiments and theoretical calculations in a wide range of scientific fields such as physics, chemistry, biology, and so on. In the MD method, the Newtonian equations of motion of classical particles are integrated numerically to reproduce a phase-space trajectory of the system. In the 1980's, several new techniques were developed for simulation at constant-temperature and/or constant-pressure to compare results of computer simulation with experimental results. The MD method for both microcanonical and canonical simulations is summarized. Then, an overview of a newly developed ISIS (Isokinetic Simulation of Soft-spheres) code and its performance on various computers including vector processors is presented. The ISIS code has a capability to make a MD simulation under constant-temperature condition by using the isokinetic constraint method. The equations of motion are integrated by a very accurate fifth-order finite differential algorithm. The bookkeeping method is also utilized to reduce the computational time. Furthermore, the ISIS code is well adopted for vector processing: speedup ratio ranged from 16 to 24 times is obtained on a VP2600/10 vector processor. DOE

A GENERALIZED BETHE-WEIZSAECKER MASS FORMULA FOR STRANGE HADRONIC MATTER
C. B. Dover (Brookhaven National Lab., Upton, NY.) and A. Gal (Hebrew Univ., Jerusalem, Israel.) Dec. 1992 34 p
(Contracts DE-FG06-90ER-40561; DE-AC02-76CH-00016)
(DE93-011010; DOE/ER-40561/096) Avail: CASI HC A03/MF A01

The Bethe-Weizsaecker nuclear mass formula is extended to strange hadronic matter composed of nucleons, lambdas, and cascade hyperons. The generalized formula contains several volume and symmetry terms constrained by phenomenologically determined lambda-nuclear, xi-nuclear, and lambda(lambda) interaction parameters and by hyperon-hyperon (lambda(lambda), lambda(xi), xi(xi)) interaction parameters suggested by One-Boson-Exchange models. We find that hypernuclei are generally unstable to lambda(lambda) yields (xi)N conversion. For strange hadronic matter we determine, as a function of the baryon number A, the line of strong-interaction stability, along which a large strangeness fraction S/A approximately 0.5-1.1 and a low charge fraction q/A approximately less than 0.2 hold, and no fission occurs. The binding energy per baryon increases monotonically to its bulk limit, B/A yields 38 MeV, S/A yields 1.1 and q/A yields 0 for the parameters adopted here assuming that the hyperon species saturate at densities similar to those of protons and neutrons in nuclei. Even in the extreme limit of vanishingly small hyperon-hyperon interaction strengths, strange hadronic matter with B/A yields 15 MeV, S/A yields 0.7 and q/A yields 0 in the bulk limit should exist, the mass formula reproduces semi-quantitatively recent mean-field calculations which implicitly assumed weak hyperon-hyperon interactions. REAL-SPACE FORMATION AND DISSIPATION DYNAMICS OF HEXAGONAL RECONSTRUCTION ON Au(100) IN AQUEOUS MEDIA AS EXPLORED BY POTENTIODYNAMIC SCANNING TUNNELING MICROSCOPY
Xiaoping Gao, Gregory J. Edens, Antoinette Hamelin, and Michael J. Weaver Apr. 1993 48 p
(Contract N00014-91-J-1409)
(AD-A266138; TR-140) Avail: CASI HC A03/MF A01

The electrode potential-induced formation and dissipation dynamics of the hexagonal ('hex') reconstruction on ordered Au(100) in perchloric and sulfuric acid electrolytes has been studied by means of in-situ scanning tunneling microscopy (STM). The real-space/real-time evolution of surface structures associated with the potential-dependent hex reversable (1 x 1) phase transition was examined on timescales down to ca 1 s by acquiring STM images during appropriate potential sweeps and steps (dubbed here 'potentiodynamic STM'). Extensive hex domains can be formed by slow cooling following flame annealing and/or by holding the potential at values significantly below the potential of zero charge for the (1 x 1) surface. The sharp removal of the reconstruction seen voltammetrically, during positive-going potential sweeps, is accompanied by rapid (less than 1 s) formation of arrays of ordered (1 x 1) clusters, created from the release of the ca 24% additional gold atoms utilized in the (5 x 27) and related hex structures compared with the (1 x 1) substrate. These clusters are significantly, twofold, larger (ca 4-6 nm) when formed in sulfuric acid electrolyte, due probably to an enhanced surface mobility in the presence of adsorbed sulfate. DTIC

THEORY OF ELEMENTARY PARTICLES AND ACCELERATOR THEORY. TASK C: EXPERIMENTAL HIGH ENERGY PHYSICS
J. E. Brau 1992 70 p
(Contract DE-FG06-85ER-40224)
(DE93-013139; DOE/ER-40224/247) Avail: CASI HC A04/MF A01

The experimental high energy physics group at the University of Oregon broadened its effort during the past year. The SLD effort extends from maintaining and operating the SLD luminosity monitor which was built at Oregon, to significant responsibility in physics analysis, such as event selection and background analysis for the left-right asymmetry measurement. The OPAL work focussed on the luminosity monitor upgrade to a silicon-tungsten calorimeter. Building on the work done at Oregon for SLD, the tungsten for this upgrade was machined by the Oregon shops and shipped to CERN for assembly. The Oregon GEM effort now concentrates on tracking, specifically silicon tracking. Oregon also has developed a silicon strip preradiator prototype and tested it in a Brookhaven beam. DOE

NUCLEAR STRUCTURE MODELS: APPLICATIONS AND DEVELOPMENT
P. B. Semmes Apr. 1993 12 p
(Contract DE-FG05-92ER-40694)
(DE93-012934; DOE/ER-40694/2) Avail: CASI HC A03/MF A01

This report summarizes the progress made during the period 1 July 1992 to 30 Apr. 1993. The study of rotational structure at moderate spins in odd-odd nuclei has continued into the A approximately 80 region. Recent experimental data for the positive parity band in Y-82, including absolute BM1 and BE2 values, are rather well described with a 'prolatish' triaxial shape and a (pi)g(sub 9/2) (direct product) (nu)g(sub 9/2) configuration. Little effect from a proton-neutron interaction has been found so far. Current studies of odd mass nuclei are mainly focussing on low spin, low energy states in the A approximately 130 region as a probe to the evolving collectivity. These projects involve direct collaboration with experimental colleagues. Finally, a view of the microscopic foundation of particle-core coupling models approached from the equation of motion method is presented. DOE

SHORT PULSE LASERS FOR GENERATION OF FIELDS EXCEEDING 100 MG
J. H. Hammer, M. Glinsky, W. Kruer, M. Tabak, S. Wilks, and J. Woodworth Nov. 1992 10 p Presented at the 6th International Conference on Megagauss Magnetic Field Generation and Related Topics, Albuquerque, NM, 9-12 Nov. 1992
(Contract W-7405-eng-48)
(DE93-013346; UCRL-JC-111540; CONF-921133-19) Avail: CASI HC A02/MF A01

We consider the use of intense, short-pulse lasers for generation of ultra-high magnetic fields. Twenty MG-level fields were observed in CO2 laser-illuminated targets, however, the recent development of Nd glass lasers capable of delivering several Joules in approximately 1 ps at intensities great er than 10(exp 18) W/cm(exp 4) opens the possibility of much higher magnetic fields (B greater tha n 100 MG). Magnetic field generation is associated with the efficient production of energetic electrons at high values of intensity x wavelength(exp 2), I(lambda)(exp 2). I(lambda) is proportional to the square of the oscillating momentum of electrons in the laser EM field. For I(lambda)(exp 2) great er than 10(exp 17) W/cm(exp 2)-microns(exp 2), the electron motion becomes nonlinear and most of the absorbed energy appears as 'hot' electrons. The absorption of laser energy has been observed to be approximately 50% at 10(exp 18) W/cm(exp 2)-microns(exp 2) and is predicted to the same or higher at 10(exp 19) W/cm(exp 2)-microns(exp 2). The hot electron temperature is much greater than the background temperatures and approaches the oscillatory energy at high I(lambda)(exp 2). The new short pulse lasers reach high values of I(lambda)(exp 2) at much higher intensity and energy density than long wavelength CO2 lasers, which should lead to higher magnetic fields. DOE

CHROMATOGRAPHIC ASSESSMENT OF HYDROGEN-BOND DONATING ABILITY Technical Report, 1 Jun. 1992 - 31 May 1993
R. Wanke, M. C. Etter, and P. W. Carr 22 Apr. 1993 8 p
(Contract N00014-89-J-1301)
(AD-A265292; TR-21-ONR) Avail: CASI HC A02/MF A01

Generally, hydrogen bonding preferentially occurs between the best donors and best acceptors in the organic solid state. Knowledge of the relative hydrogen-bond acidity and basicity can, therefore, be used in molecular crystal engineering. A liquid chromatography method was developed to assess the hydrogen-bond acidity of potential hydrogen-bond donors used in cocrystallizations. Hydrogen-bond donor solutes are chromatographed on a poly(vinylpyridine - divinylbenzene) column under two different sets of mobile phase conditions. The relative retention is proportional to the hydrogen-bond acidity of the solute and therefore, provides an a priori measure of the hydrogen-bond acidity of a potential cocrystal component. DTIC

ATOMIC-SCALE IMAGING OF SURFACES AND INTERFACES. MATERIALS RESEARCH SOCIETY SYMPOSIUM PROCEEDINGS, VOLUME 295
David K. Biegelsen, David J. Smith, and S. Y. Tong 1992 297 p Proceedings held in Boston, MA, 30 Nov. - 2 Dec. 1992
(Contract N00014-93-J-0023)
(AD-A265674) Avail: CASI HC A13/MF A03

The gap between imagining and imaging is getting ever smaller. The Atomic-Scale Imaging of Surfaces and Interfaces, Symposium W at the 1992 MRS Fall Meeting in Boston, Massachusetts, brought together researchers using state-of-the-art imaging techniques capable of resolving atomic features. Methods represented were scanning tunneling microscopy (STM), atomic force microscopy (AFM), low energy electron microscopy (LEEM), transmission (TEM) and reflection (REM) electron microscopy, scanning electron microscopy (SEM), atom probe field ion microscopy (APFIM or POSAP), high and low energy external source electron holographies, and internal source electron holographies. Some highlights from the STM papers included discussions of the limitations and future potential of STM as well as current findings. Several papers presented work with STM at elevated temperatures. Jene Golovchenko reviewed STM work showing cooperative diffusion events (Pb on Ge) involving many tens of substrate atoms. Don Eigler focused on atomic manipulation and some of its uses to enable fundamental studies of small atomic clusters. DTIC

(Contract N00014-92-J-1277)
(AD-A266029) Avail: CASI HC A01/MF A01

Most of the effort the first year of this program was devoted to the building of required instrumentation. The thin metal films required necessitated having a feed-back controller for the multihearth electron beam evaporator in the molecular beam epitaxy (MBE) system. Thus, one of our initial projects under this grant was the installation of a Inficon Sentinel controller in the MBE system. This project was successfully completed. The new electron beam evaporator, with its controller, will allow us to evaporate Pt and Au and Ge in the deposition chamber in addition to Si and Co which were already available. MBE growth of SiGe alloys was started and we expect to start ballistic electron emission microscopy (BEEM) studies of metal layers on SiGe alloys this summer. A key part is the ultra-high vacuum (UHV) BEEM studies of MBE grown material. After debating the alternatives, it was decided to install the UHV STM directly into the MBE chamber after testing it in air. DTIC

SOLVENT DYNAMICAL EFFECTS IN ELECTRON TRANSFER: MOLECULAR DYNAMICS SIMULATIONS OF REACTIONS IN METHANOL
Donald K. Phelps, Michael J. Weaver, and Branka M. Ladanyi Apr. 1993 41 p
(Contract N00014-91-J-1409)
(AD-A266061; TR-139) Avail: CASI HC A03/MF A01

Molecular-dynamics simulations of activated electron-transfer (ET) reactions in methanol have been undertaken in order to explore the physical nature of the solvent dynamics coupled to ET barrier crossing, and to probe some underlying reasons for the facile kinetics observed in this solvent. The reactant is modeled by a pair of Lennard-Jones (LJ) spheres in contact, of varying diameter (4 or 5 A), and containing a univalent charge (cation or anion) on one site so to probe possible effects of the ionic charge sign. Following equilibration, the collective solvent response to a sudden charge transfer between the spherical sites is followed, and described in terms of the response function C(t), describing the difference in the solvent-induced electrostatic potential between the initial and final solute states. In all cases, the C(t) curves exhibit a very rapid (50-100 fs) initial decay component associated with hydroxyl inertial motion, followed by components arising from hydrogen-bond librational and diffusive motions. During the past year, the HELIOS work drew to a close. In the first results from the electron-muon pair studies, no anomalous sources were seen. The final results and uncertainties are being set. First data from CMD2 will allow improvement of some phi branching ratios including some improved limits on forbidden decays. The engineering run for E865 is scheduled for June and July of 1993. The principal efforts of Task B, the Fermilab program, have been the completion of the analysis of the 1987-88 data with resulting publications, completion of the 1990-91 data run, and the beginning of the analysis of the 1990-91 data. In addition, the Task B group is taking a leadership role in developing a proposal to Fermilab for the upgrade of the CDF silicon vertex detector in preparation for the 1995 data run. Task C has recently submitted results of its fractionally charged particle searches. These results will place new upper limits on the abundance of naturally-occurring fractionally-charged particles in various materials. This group has recently been approved by the Brookhaven management for an exposure of their p-i-n diodes in a high intensity proton beam. This measurement, along with its subsequent analysis, will complete the program. Task D concerned itself with silicon drift chamber studies for the SSC. Task E was devoted to studies of electronics for the GEM Level 1 liquid Ar calorimeter trigger. DOE

Avail: CASI HC A03/MF A01

The BCS mechanism, augmented by an ad hoc, but reasonable symmetry breaking mechanism, describes both the quark and lepton masses and is consistent with the constraints imposed by the Cabbibo-Kobayashi-Maskawa mixing matrix. This mechanism may be incorporated into the study of various extensions of the Standard Model such as SUSY SU(5). The symmetry breaking at the unification scale is related to that at experimentally accessible scales by running the coefficients of the terms in the mass matrices characterized by their symmetries. IN-REACTOR TESTING OF THE CLOSED CYCLE GAS CORE REACTOR: THE NUCLEAR LIGHT BULB CONCEPT
R. O. Gauntt, S. A. Slutz, G. A. Harms, T. S. Latham (United Technologies Research Center, East Hartford, CT.), W. C. Roman (United Technologies Research Center, East Hartford, CT.), and R. J. Rodgers (United Technologies Research Center, East Hartford, CT.) 16 Oct. 1992 11 p Presented at the 10th Symposium on Space Nuclear Power and Propulsion, Albuquerque, NM, 10-14 Jan. 1993
(Contract DE-AC04-76DP-00789)
(DE93-004053; SAND-92-1462C; CONF-930103-24) Avail: CASI HC A03/MF A01 (US Sales Only)

The Nuclear Light Bulb (NLB) concept is an advanced closed cycle space propulsion rocket engine design that offers unprecidented performance characteristics in terms of specific impulse (greater than 1800 s) and thrust (greater than 445 kN). The NLB is a gas-core nuclear reactor making use of thermal radiation from a high temperature U-plasma core to heat the hydrogen propellant to very high temperatures (greater than 4000 K). Analyses performed in support of the design of in-reactor tests that are planned to be performed in the Annular Core Research Reactor (ACRR) at Sandia National Laboratories in order to demonstrate the technical feasibility of this advanced concept are described. The tests will examine the stability of a hydrodynamically confined fissioning U-plasma under steady and transient conditions. Testing will also involve study of propellant heating by thermal radiation from the plasma and materials performance in the nuclear environment of the NLB. The analyses presented include neutronic performance studies and U-plasma radiation heat-transport studies of small vortex-confined fissioning U-plasma experiments that are irradiated in the ACRE. These analyses indicate that high U-plasma temperatures (4000 to 9000 K) can be sustained in the ACRE for periods of time on the order of 5 to 20 s. These testing conditions are well suited to examine the stability and performance requirements necessary to demonstrate the feasibility of this concept. DOE

EXPERIMENTAL EFFORTS AND RESULTS IN FINDING NEW HEAVY SCINTILLATORS
S. E. Derenzo and W. W. Moses Sep. 1992 11 p Presented at the Crystal 2000 International Workshop on Heavy Scintillators for Scientific and Industrial Applications, Chamonix, France, 22-26 Sep. 1992
(Contract DE-AC03-76SF-00098)
(DE93-010406; LBL-33295; CONF-9209253-4) Avail: CASI HC A03/MF A01

New heavy scintillators are being discovered with increasing frequency. In recent years NaI(TI) (with its high light output and energy resolution) has been joined by BCO (with its high stopping power), BaF2 (with its excellent timing resolution), and CeF3 (with its speed and short Moliere radius). More than 10 potentially useful scintillators have been under development in the past five years, such as PbSO4 and Lu2SiO5(Ce). We tabulate the characteristics of these and other scintillators, including wavelength, luminous efficiency, decay time, and initial intensity. We describe a search strategy and the prospects for finding the 'ideal' heavy scintillator, which would combine the light output of NAI(TI) and CsI(TI), the stopping power of BGO, and the speed of BaF2 and ZnO(Ga). HIGH-ENERGY DENSITY PHYSICS AT LOS ALAMOS
P. Byrnes, ed. Mar. 1993 27 p
(Contract W-7405-eng-36)
(DE93-010271; LALP-93-17) Avail: CASI HC A03/MF A01

This brochure describes the facilities of the Above Ground Experiments 2 (AGEX 2) and the Inertial Confinement Fusion (ICF) programs at Los Alamo. Combined, these programs represent, an unparalleled capability to address important issues in high-energy density physics that are critical to the future defense, energy, and research needs of the United States. The mission of the AGEX 2 program at Los Alamos is to provide additional experimental opportunities for the nuclear weapons program. For this purpose we have assembled at Los Alamos the broadest array of high-energy density physics facilities of any laboratory in the world. Inertial confinement fusion seeks to achieve thermonuclear burn on a laboratory scale through the implosion of a small quantity of deuterium and tritium fuel to very high pressure and temperature. The Los Alamos ICF program is focused on target physics. With the largest scientific computing center in the world, We can perform calculations of unprecedented sophistication and precision. We field experiments at facilities worldwide--including our own Trident and Mercury lasers--to confirm our understanding and to provide the necessary data base to proceed toward the historic goal of controlled fusion in the laboratory. The ultrahigh magnetic fields produced in our high explosive pulsed-power generators can be used in a wide variety of solid state physics and temperature superconductor studies. The structure and dynamics of planetary atmospheres can be simulated through the compression of gas mixtures. DOE

AN EXPERIMENTAL PROGRAM FOR COLLECTIVE ACCELERATION OF IONS USING INTENSE RELATIVISTIC ELECTRON BEAMS
T. Vijayan, P. Raychowdhury, and S. K. Iyengar (Bhabha Atomic Research Centre, Bombay, India.) 1992 68 p
(DE93-612205; BARC-1992/E/008) Avail: CASI HC A04/MF A01 (US Sales Only)

A program of collective ion acceleration using intense relativistic electron beam (IREB) of 0.25-1MeV, 6-80kA, 60ns on the Kilo Ampere Linear Injector (KALI) systems to accelerate light and heavy ions to high energies approaching GeV with currents over tens of amperes, is envisaged. The accelerator will make use of the intense space-charge field of electron beam in vacuum for accelerating ions which are injected into it. For ion injection, various alternatives, such as, localized gas puff, dielectric insert, laser plasma, etc. were considered as present and long-term objectives. Among the variety of diagnostic methods chosen for characterizing the accelerated ions include range-energy in foil, CR-39 track detector, nuclear activation technique and time-of-flight for energy and species determination; ion Faraday cup for current measurement; and Thomson parabola analyzer for determining the post-acceleration charge-state. In the proposed MAHAKALI collective accelerator, protons of energy over 10 MeV and higher charge state metal ions around a GeV are predicted using a REB of 1MeV, 30kA, 60ns from KALI-5000. In present experiments using KALI-200 with REB parameters of 250keV, 60kA, 80ns, protons over a MeV and carbon and fluorine ions respectively for 12MeV and 16MeV in significant currents were accelerated. DOE

A CRITICAL ASSEMBLY DESIGNED TO MEASURE NEUTRONIC BENCHMARKS IN SUPPORT OF THE SPACE NUCLEAR THERMAL PROPULSION PROGRAM
E. J. Parma, R. M. Ball (Babcock and Wilcox Co., Lynchburg, VA.), G. S. Hoovler (Babcock and Wilcox Co., Lynchburg, VA.), E. C. Selcow (Brookhaven National Lab., Upton, NY.), and R. J. Cerbone (Brookhaven National Lab., Upton, NY.) 1992 10 p Presented at the 10th Symposium on Space Nuclear Power and Propulsion, Albuquerque, NM, 10-14 Jan. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC04-76DP-00789)
(DE92-040974; SAND-92-1407C; CONF-930103-12) Avail: CASI HC A02 (US Sales Only)

A reactor designed to perform criticality experiments in support of the Space Nuclear Thermal Propulsion program is currently in operation at the Sandia National Laboratories' reactor facility. The reactor is a small, water-moderated system that uses highly enriched uranium particle fuel in a 19-element configuration. Its purpose is to obtain neutronic measurements under a variety of experimental conditions that are subsequently used to benchmark reactor-design computer codes. Brookhaven National Laboratory, Babcock & Wilcox, and Sandia National Laboratories participated in determining the reactor's performance requirements, design, follow on experimentation, and in obtaining the licensing approvals. Brookhaven National Laboratory is primarily responsible for the analytical support, Babcock & Wilcox the hardware design, and Sandia National Laboratories the operational safety. All of the team members participate in determining the experimentation requirements, performance, and data reduction. Initial criticality was achieved in October 1989. An over-all description of the reactor is presented along with key design features and safety-related aspects. DOE

DYNAMICS OF ION ACCELERATION IN ELECTRON FLUX BY A VIRTUAL CATHODE POTENTIAL [INAMIKA USKORENIYA IONOV V POTOKE EHIEKTRONOV S VIRTUAL'NYM KATODOM]
V. V. Dolgopolov, Y. V. Kirichenko, S. S. Romanov, and Y. N. Tkach 1991 12 p In RUSSIAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-620978; KFTI-91-37) Avail: CASI HC A03 (US Sales Only)

Ion acceleration was investigated theoretically. Ions are described by the Vlasov equation. It was shown that the appearance of ions in a drift region may lead to an accelerated movement of the virtual cathode and following this, a potential hole slope without a considerable decrease of this slope change rate. This leads to an effective ion acceleration. DOE

MONOCHROMATOR SP-017. THE RESULTS OF THE FIRST EXPERIMENTS [MONOKHROMATOR SP-017. REZUL'TATY PERVYKH EHKSPERIMENTOV]

A. A. Shvedov, O. Y. Goryunov, and V. V. Ostashko et al 1992 15 p In RUSSIAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-617463; KIYal-92-7) Avail: CASI HC A03 (US Sales Only)

The results of the first experiments on parameter investigation of monochromator SP-017 as well as the energetic resolution of telescopes consisting of Si-detectors on beams of monochromated deuterons and alpha-particles are presented. The experiments showed that in the dispersion condition the monochromator SP-017 allows one to obtain the nonmonochromaticity 1.5 x 10(exp -3). It was established that the peak width of deuteron elastic scattering E(sub d) = 19.7 MeV in the Al-27 + alpha-reaction, caused by the intrinsic resolution of Ge-detector and beam nonmonochromaticity was 46 keV. The energetic telescope resolution of Si-detectors is delta-E(sub alpha) = 150 keV at E(sub alpha) = 39.5 MeV. DOE

FULLY COUPLED NEUTRONIC AND HYDRODYNAMIC ANALYSIS OF SPACE NUCLEAR REACTOR REENTRY ACCIDENTS

J. J. Buksa, J. S. Elson, D. B. Kothe, J. M. McGhee, J. E. Morel, R. T. Perry, and W. J. Rider 1992 7 p Presented at the 1993 International Simulators Conference on High Performance Computing, Arlington, VA, 29 Mar. - 1 Apr. 1993
(Contract W-7405-eng-36)
(DE93-005459; LA-UR-92-4382; CONF-930372-2) Avail: CASI HC A02/MF A01 (US Sales Only)

A method is described for determining the fully coupled neutronic/hydrodynamic response of a space nuclear reactor upon reentry and impact. The code system NIKE-R/PAGOSA is used to accomplish this. This is in contrast to the typical methodology that computes these responses in a decoupled manner. The use of NIKE-R/PAGOSA will allow the seamless description of the phenomena without direct human intervention. This methodology is enabled by the use of modern supercomputers (CM-200). Two examples of this capability are presented: an impaction event modeled with hydrodynamics only (PAGOSA) with the neutron multiplication constant calculated at selected times, and a fully coupled simulation of a reactor immersed in water with its physical disassembly due to its supercritical configuration. REPORT OF THE THIRD SEMINAR ON NUCLEAR PHYSICS AT THE ENERGY REGION OF THE JAERI TANDEM-BOOSTER ACCELERATOR

Akira Iwamoto, ed., Masumi Oshima, ed., Hiroshi Ikezoe, ed., Yuichiro Nagame, ed., and Nobuo Shinohara, ed. (Japan Atomic Energy Research Inst., Tokai.) Sep. 1992 121 p Seminar held in Tokai, Japan, 27-28 Feb. 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-754330; JAERI-M-92-138) Avail: Issuing Activity (Department of Energy (DOE))

A seminar on new experiments to be studied and new experimental apparatus suitable for the Japan Atomic Energy Research Institute (JAERI) tandem-booster accelerator under construction was held at Tokai Research Establishment of JAERI in the period from 27-28 Feb. 1992. Sixty eight participants from universities and from JAERI attended to discuss the following items: (1) physics at low temperature, (2) nuclear structure at high spin and at high excitation energy, (3) application of unstable beam and their spectroscopy, (4) nuclear reaction at intermediate energy, and (5) new facilities. A FACILITY FOR TESTING 10- TO 100-kWe SPACE POWER REACTORS

W. F. Carlson and E. J. Bitten Jun. 1992 9 p Presented at the 10th Symposium on Space Nuclear Power and Propulsion, Albuquerque, NM, 10-14 Jan. 1993 Limited Reproducibility: More than 20% of this document may be affected by poor print and microfiche quality
(Contract DE-AC06-87RL-10930)
(DE92-040420; WHC-SA-1536; CONF-930103-9) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

This paper describes an existing facility that could be used in a cost-effective manner to test space power reactors in the 10 to 100-kWe range before launch. The facility has been designed to conduct full power tests of 100-kWe SP-100 reactor systems and already has the structural feature that would be required for lower power testing. The paper describes a reasonable scenario starting with the acceptance at the test site of the unfueled reactor assembly and the separately shipped nuclear fuel. After fueling the reactor and installing it in the facility, cold critical tests are performed, and the reactor is then shipped to the launch site. The availability of this facility represents a cost-effective means of performing the required prelaunch test program. DOE

DEVELOPMENT OF PLASTIC CAPSULE FOR RESEARCH REACTOR IRRADIATION

Kenji Arigane, Shigeo Shida, Heita Waragai, Isao Aoyama, Hidetake Takahashi, and Tadao Seguchi (Japan Atomic Energy Research Inst., Takasaki.) Jun. 1992 28 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-753186; JAERI-M-92-078) Avail: CASI HC A03

New irradiation capsule for the research reactor was developed using a radiation resistant polymer, Polyethylene-2,6-Naphthalate (PEN). This capsule has several merits such as low activity after irradiation, low price by mass production using injection moulding, and good irradiation performance for application to 12 hours irradiation in Japan Research Reactor No. 4 (JRR-4). Using this capsule, more efficient irradiation can be done because the sample can be taken off from the capsule immediately after irradiation, and this PEN capsule can be replaced with ordinary aluminum capsule for JRR-4 irradiation. The development of PEN capsule and the irradiation tests are described. DOE

The results of the joint utilization of the nuclear reactor 'Yayoi' and the electron beam accelerator in the Nuclear Engineering Research Laboratory, University of Tokyo, in fiscal year 1991 are summarized. The Yayoi was operated smoothly throughout the year, and the number of research themes, for which the reactor Yayoi was jointly utilized, and the related themes reached 21 cases. After the linear accelerator was reconstructed as the twin linac, the joint utilization was resumed in October 1989, and the number of research themes was 15 cases. In addition to the utilization reports, the reports of 15 cases of Yayoi Study Meetings held in fiscal year 1991 are collected. DOE

APPLICATIONS OF IN-SITU ELLIPSOMETRY TO MICROWAVE ELECTRON CYCLOTRON RESONANCE PLASMA PROCESSES
Technical Report
Y. Z. Hu, J. Joseph, and E. A. Irene 4 May 1993 15 p
(Contract N00014-89-J-1178)
(AD-A265197; TR-57) Avail: CASI HC A03/MF A01

In-situ static spectroscopic ellipsometry (SE) is a powerful method for characterizing the optical properties and structure of multilayered thin films. However, the commonly used rotating element ellipsometry takes about 10 min for each spectral measurement. Using only a single wavelength gives less information, but each measurement time reduces to about 5 sec. It is shown that a combination of the techniques was adequate to investigate the plasma processes. Spectroscopic ellipsometry measurements for Si, Ge, InP, InSb, and GaAs showed that for properly selected photon energy ranges, the dependence of the dielectric functions on temperatures minimum while the sensitivity to surface modifications is high. The ECR plasma oxidation of Si is discussed first, since it is the simplest case, and then attention is given to more complex example of ECR plasma ion bombardment induced oxidation and damage in single crystal Ge. A set of experiments is reviewed which makes use of the emission of muonic deuterium from the surface of a layer of solid hydrogen. The behavior of muons in a solid target system has been studied via detection of muon decay electrons, muonic x-rays, and fusion products (neutrons and charged particles). The emission of muonic deuterium is understood to result from the Ramsauer-Townsend scattering minimum. The energy distribution of the emitted atoms ranges from tenths of eV to about 10eV, and can be controlled to some extent. A proposal is described to use muonic tritium emission to measure the energy dependence of muonic molecular formation. DOE

SPECTRUM ANALYSIS IN BEAM DIAGNOSTICS
S. Y. Zhang and W. T. Weng 23 Apr. 1993 35 p
(Contract DE-AC02-76CH-00016)
(DE93-013401; BNL-48907) Avail: CASI HC A03/MF A01

In this article, we discuss fundamentals of the spectrum analysis in beam diagnostics, where several important particle motions in a circular accelerator are considered. The properties of the Fourier transform are presented. Then the coasting and the bunched beam motion in both longitudinal and transverse are studied. The discussions are separated for the signal particle, multiple particle, and the Schottky noise cases. To demonstrate the interesting properties of the beam motion spectrum, time domain functions are generated, and then the associated spectra are calculated and plotted. In order to show the whole picture in a single plot, some data have been scaled, therefore they may not be realistic in an accelerator. DOE

ION SHAKING IN THE 200 MeV XLS-RING
E. Bozoki and S. L. Kramer 1992 4 p Presented at the 3rd European Particle Accelerator Conference (EPAC-3): Accelerators for Special Applications, Berlin, Germany, 24-28 Mar. 1992
(Contract DE-AC02-76CH-00016)
(DE93-014057; BNL-48679; CONF-920315-47) Avail: CASI HC A01/MF A01

It has been shown that ions, trapped inside the beam's potential, can be removed by the clearing electrodes when the amplitude of the ion oscillation is increased by vertically shaking the ions. We will report on a similar experiment in the 200 MeV XLS ring. The design of the ion clearing system for the ring and the first results obtained were already reported. In the present series of experiments, RF voltage was applied on a pair of vertical strip-lines. The frequency was scanned in the range of the ion (from H2 to CO2) bounce frequencies in the ring (1-10 MHz). The response of the beam size, vertical betatron tune, and lifetime was studied. DOE

METHOD AND APPARATUS FOR POLARIZATION-MAINTAINING FIBER OPTICAL AMPLIFICATION WITH ORTHOGONAL POLARIZATION OUTPUT Patent Application
Irl N. Duling, inventor (to Navy) and Ronald D. Esman, inventor (to Navy) 15 Mar. 1993 38 p
(AD-D015756; US-Patent-Appl-SN-031251) Avail: CASI HC A03/MF A01

A single-polarization fiber optical amplifier and corresponding method is provided capable of amplifying an optical input signal by a fiber optic amplifier constructed of fiber which may be non-polarization-maintaining. The single-polarization fiber optical amplifier provides a direction-selective coupler which receives an optical input at a first port and outputs an optical output at a second port. A fiber optic amplifier is operatively connected to the direction-selective coupler at a bidirectional port for amplifying the optical input. A retro-reflecting orthogonal polarization converter is operatively connected to the fiber optic amplifier, reflecting the amplified optical input from the fiber optic amplifier in a return direction through the fiber optic amplifier and in an orthogonal polarization to the amplified optical input. The direction-selective coupler outputs the reflected amplified orthogonal optical input at the second port as the optical output of the direction-selective coupler. DTIC

TECHNIQUE TO PREPARE HIGH-REFLECTANCE OPTICAL FIBER BRAGG GRATINGS WITH SINGLE EXPOSURE IN-LINE ON FIBER DRAW TOWER Patent Application
Charles Askins, inventor (to Navy) and Edward Friebele, inventor (to Navy) 21 Jan. 1993 25 p
(AD-D015757; US-Patent-Appl-SN-006544) Avail: CASI HC A03/MF A01

A process for making an optical reflection grating in a glass fiber includes exposing an unjacketed optic fiber to a single writing pulse from a pair of interfering light beams that form an interference pattern in the fiber. A novel optical fiber has at least one optical grating with a preselected Bragg spacing in at least one region of the fiber, with a periodic modulation in its index of refraction, with high thermal stability and narrow linewidth. A process for making an array of optical reflection gratings in a glass fiber includes exposing a fiber to a plurality of writing pulse from a pair of interfering light beams that form an interference pattern in the fiber, where these pulses are applied sequentially as the fiber is drawn from a draw furnace. A novel optical fiber has a plurality of unspliced gratings with high thermal stability and narrow linewidth. Author (DTIC)

THE SECOND INTERNATIONAL WORKSHOP ON SQUEEZED STATES AND UNCERTAINTY RELATIONS

D. Han, ed., Y. S. Kim (Maryland Univ., College Park.), and V. I. Manko (Academy of Sciences, USSR, Moscow.) Washington 1993 415 p Workshop held in Moscow, Russia, 25-29 May 1992
(Contract NAS5-30376)
(NASA-CP-3219; Rept-93B00088; NAS 1.55:3219) Avail: CASI HC A18/MF A04

This conference publication contains the proceedings of the Second International Workshop on Squeezed States and Uncertainty Relations held in Moscow, Russia, on 25-29 May 1992. The purpose of this workshop was to study possible applications of squeezed states of light. The Workshop brought together many active researchers in squeezed states of light and those who may find the concept of squeezed states useful in their research, particularly in understanding the uncertainty relations. It was found at this workshop that the squeezed state has a much broader implication than the two-photon coherent states in quantum optics, since the squeeze transformation is one of the most fundamental transformations in physics. For individual titles, see N94-10565 through N94-10612.

A PHASEONIUM MAGNETOMETER: A NEW OPTICAL MAGNETOMETER BASED ON INDEX ENHANCED MEDIA

Marlan O. Scully, Michael Fleischauer (Ludwig-Maximilians-Univ., Munich, Germany.), and Martin Graf (Ludwig-Maximilians-Univ., Munich, Germany.) *In* NASA. Goddard Space Flight Center, The Second International Workshop on Squeezed States and Uncertainty Relations 1993 p 5-15 (For primary document see N94-10564 01-74)
Avail: CASI HC A03/MF A04

An optical magnetometer based on quantum coherence and interference effects in atoms is proposed. The sensitivity of this device is potentially superior to the present state-of-the-art devices. Optimum operating conditions are derived, and a comparison to standard optical pumping magnetometers is made. Author (revised)

SMOOTHLY DEFORMED LIGHT

Stig Stenholm *In* NASA. Goddard Space Flight Center, The Second International Workshop on Squeezed States and Uncertainty Relations 1993 p 17-23 (For primary document see N94-10564 01-74)
Avail: CASI HC A02/MF A04

A single mode cavity is deformed smoothly to change its electromagnetic eigenfrequency. The system is modeled as a simple harmonic oscillator with a varying period. The Wigner function of the problem is obtained exactly by starting with a squeezed initial state. The result is evaluated for a linear change of the cavity length. The approach to the adiabatic limit is investigated. The maximum squeezing is found to occur for smooth change lasting only a fraction of the oscillational period. However, only a factor of two improvement over the adiabatic result proves to be possible. The sudden limit cannot be investigated meaningfully within the model. Author (revised)

QUANTUM NOISE AND SQUEEZING IN OPTICAL PARAMETRIC OSCILLATOR WITH ARBITRARY OUTPUT COUPLING

Sudhakar Prasad (New Mexico Univ., Albuquerque.) *In* NASA. Goddard Space Flight Center, The Second International Workshop on Squeezed States and Uncertainty Relations 1993 p 35-48 (For primary document see N94-10564 01-74)
(Contract DE-FG02-90ER-14119)
Avail: CASI HC A03/MF A04

The redistribution of intrinsic quantum noise in the quadratures of the field generated in a sub-threshold degenerate optical parametric oscillator exhibits interesting dependences on the individual output mirror transmittances, when they are included exactly. We present a physical picture of this problem, based on mirror boundary conditions, which is valid for arbitrary transmittances. Hence, our picture applies uniformly to all values of the cavity Q factor representing, in the opposite extremes, both perfect oscillator and amplifier configurations. Beginning with a classical second-harmonic pump, we shall generalize our analysis to the finite amplitude and phase fluctuations of the pump. Author (revised)

DISTURBANCE, THE UNCERTAINTY PRINCIPLE AND QUANTUM OPTICS

Hans Martens and Willem M. deMuynck *In* NASA. Goddard Space Flight Center, The Second International Workshop on Squeezed States and Uncertainty Relations 1993 p 49-54 (For primary document see N94-10564 01-74)
Avail: CASI HC A02/MF A04

It is shown how a disturbance-type uncertainty principle can be derived from an uncertainty principle for joint measurements. To achieve this, we first clarify the meaning of 'inaccuracy' and 'disturbance' in quantum mechanical measurements. The case of photon number and phase is treated as an example, and it is applied to a quantum non-demolition measurement using the optical Kerr effect. Author (revised)

ONE DIMENSIONAL REPRESENTATIONS IN QUANTUM OPTICS

J. Janszky, P. Adam, I. Foldesi, and An. V. Vinogradov (Academy of Sciences, USSR, Moscow.) *In* NASA. Goddard Space Flight Center, The Second International Workshop on Squeezed States and Uncertainty Relations 1993 p 55-60 (For primary document see N94-10564 01-74)
(Contract NRFH-1444)
Avail: CASI HC A02/MF A04

The possibility of representing the quantum states of a harmonic oscillator not on the whole alpha-plane but on its one dimensional manifolds is considered. It is shown that a simple Gaussian distribution along a straight line describes a quadrature squeezed state while a similar Gaussian distribution along a circle leads to the amplitude squeezed state. The connection between the one dimensional representations and the usual Glauber representation is discussed. Author (revised)

HARMONIC OSCILLATOR INTERACTION WITH SQUEEZED RADIATION
V. V. Dodonov and D. E. Nikonov *In* NASA. Goddard Space Flight Center, The Second International Workshop on Squeezed States and Uncertainty Relations 1993 p 61-70 (For primary document see N94-10564 01-74)
Avail: CASI HC A02/MF A04

Although the problem of electromagnetic radiation by a quantum harmonic oscillator is considered in textbooks on quantum mechanics, some of its aspects have remained unclear until now. By this, we mean that usually the initial quantum states of both the oscillator and the field are assumed to be characterized by a definite energy level of the oscillator and definite occupation numbers of the field modes. In connection with growing interest in squeezed states, it would be interesting to analyze the general case when the initial states of both subsystems are arbitrary superpositions of energy eigenstates. This problem was considered in other work, where the power of the spontaneous emission was calculated in the case of an arbitrary oscillator's initial state, but the field was initially in a vacuum state. In the present article, we calculate the rate of the oscillator average energy, squeezing, and correlation parameter change under the influence of an arbitrary external radiation field. Some other problems relating to the interaction between quantum particles (atoms) or oscillators where the electromagnetic radiation is an arbitrary (in particular squeezed) state were investigated. PHOTON NUMBER AMPLIFICATION/DUPLICATION THROUGH PARAMETRIC CONVERSION
G. M. DAriano, C. Macchiavello, and M. Paris *In* NASA. Goddard Space Flight Center, The Second International Workshop on Squeezed States and Uncertainty Relations 1993 p 71-84 (For primary document see N94-10564 01-74)
Avail: CASI HC A03/MF A04

The performance of parametric conversion in achieving number amplification and duplication is analyzed. It is shown that the effective maximum gains G(sub *) remain well below their integer ideal values, even for large signals. Correspondingly, one has output Fano factors F(sub *) which are increasing functions of the input photon number. On the other hand, in the inverse (deamplifier/recombiner) operating mode quasi-ideal gains G(sub *) and small factors F(sub *) approximately equal to 10 percent are obtained. Output noise and non-ideal gains are ascribed to spontaneous parametric emission. Author (revised)

SQUEEZING IN PHASE-CONJUGATED RESONANCE FLUORESCENCE
Henk F. Arnoldus *In* NASA. Goddard Space Flight Center, The Second International Workshop on Squeezed States and Uncertainty Relations 1993 p 111-116 (For primary document see N94-10564 01-74)
Avail: CASI HC A02/MF A04

Emission of resonance fluorescence by an atom near the surface of a four-wave mixing phase conjugator is considered. The dipole radiation field, regarded as a Heisenberg-operator field, is decomposed into plane waves with the aid of Weyl's representation of the Green's function for the wave equation. Each plane-wave component which is incident on the surface of the nonlinear medium, is reflected as its phase-conjugate image. Summation of all reflected plane waves then yields the phase conjugate replica of the incident dipole radiation. This field adds to the radiation which is emitted by the atom into the direction away from the medium. The condition under which squeezing occurs in the emitted resonance fluorescence is investigated. Author

PHASING OPERATOR FOR TWO OSCILLATORS IN CLASSICAL FIELD **c72**

Jong-Jean Kim, Je-Hwan Koo, and Dong-Jae Bae (Pohang Inst. of Science and Technology, Republic of Korea.) *In* NASA. Goddard Space Flight Center, The Second International Workshop on Squeezed States and Uncertainty Relations 1993 p 143-148 (For primary document see N94-10564 01-74)
Avail: CASI HC A02/MF A04

The origin of Dicke cooperative states was studied by considering two harmonic oscillators driven by a common field of radiation. The origin is assumed for superradiance in a system of molecules where no mutual interactions exist, but all of the molecules encounter the same field of radiation. A phasing operator as Phi(sub Nu) equals D(alpha) + P(sub Nu)D(alpha), where D(alpha) is the displacing operator and P(sub Nu) the projection operator for constant energy Nu for two oscillators, was derived. The eigenstates of the phasing operator Phi are found to show a finite correlation as in the Dicke cooperative states. Author (revised)

GENERALISED SQUEEZING AND INFORMATION THEORY APPROACH TO QUANTUM ENTANGLEMENT c77
A. Vourdas *In* NASA. Goddard Space Flight Center, The Second International Workshop on Squeezed States and Uncertainty Relations 1993 p 149-156 (For primary document see N94-10564 01-74)
Avail: CASI HC A02/MF A04

It is shown that the usual one- and two-mode squeezing are based on reducible representations of the SU(1,1) group. Generalized squeezing is introduced with the use of different SU(1,1) rotations on each irreducible sector. Two-mode squeezing entangles the modes and information theory methods are used to study this entanglement. The entanglement of three modes is also studied with the use of the strong subadditivity property of the entropy. Author (revised)

STUDY OF EINSTEIN-PODOLSKY-ROSEN STATE FOR SPACE-TIME VARIABLES IN A TWO PHOTON INTERFERENCE EXPERIMENT c72
Y. H. Shih, A. V. Sergienko, and M. H. Rubin *In* NASA. Goddard Space Flight Center, The Second International Workshop on Squeezed States and Uncertainty Relations 1993 p 163-176 (For primary document see N94-10564 01-74)
Avail: CASI HC A03/MF A04

A pair of correlated photons generated from parametric down conversion was sent to two independent Michelson interferometers. Second order interference was studied by means of a coincidence measurement between the outputs of two interferometers. The reported experiment and analysis studied this second order interference phenomena from the point of view of Einstein-Podolsky-Rosen paradox. The experiment was done in two steps. The first step of the experiment used 50 psec and 3 nsec coincidence time windows simultaneously. The 50 psec window was able to distinguish a 1.5 cm optical path difference in the interferometers. The interference visibility was measured to be 38 percent and 21 percent for the 50 psec time window and 22 percent and 7 percent for the 3 nsec time window, when the optical path difference of the interferometers were 2 cm and 4 cm, respectively. By comparing the visibilities between these two windows, the experiment showed the non-classical effect which resulted from an E.P.R. state. The second step of the experiment used a 20 psec coincidence time window, which was able to distinguish a 6 mm optical path difference in the interferometers. The interference visibilities were measured to be 59 percent for an optical path difference of 7 mm. This is the first observation of visibility greater than 50 percent for a two interferometer E.P.R. experiment which demonstrates nonclassical correlation of space-time variables. Author (revised)

ON A LAGRANGE-HAMILTON FORMALISM DESCRIBING POSITION AND MOMENTUM UNCERTAINTIES c67
Dieter Schuch *In* NASA. Goddard Space Flight Center, The Second International Workshop on Squeezed States and Uncertainty Relations 1993 p 177-182 Sponsored in part by Deutsche Forschungsgemeinschaft (For primary document see N94-10564 01-74)
Avail: CASI HC A02/MF A04

According to Heisenberg's uncertainty relation, in quantum mechanics it is not possible to determine, simultaneously, exact values for the position and the momentum of a material system. Calculating the mean value of the Hamiltonian operator with the aid of exact analytic Gaussian wave packet solutions, these uncertainties cause an energy contribution additional to the classical energy of the system. For the harmonic oscillator, e.g., this nonclassical energy represents the ground state energy. It will be shown that this additional energy contribution can be considered as a Hamiltonian function, if it is written in appropriate variables. With the help of the usual Lagrange-Hamilton formalism known from classical particle mechanics, but now considering this new Hamiltonian function, it is possible to obtain the equations of motion for position and momentum uncertainties. QUANTUM ENTROPY AND UNCERTAINTY FOR TWO-MODE SQUEEZED, COHERENT AND INTELLIGENT SPIN STATES c77
C. Aragone and D. Mundarain *In* NASA. Goddard Space Flight Center, The Second International Workshop on Squeezed States and Uncertainty Relations 1993 p 193-208 (For primary document see N94-10564 01-74)
Avail: CASI HC A03/MF A04

We compute the quantum entropy for monomode and two-mode systems set in squeezed states. Thereafter, the quantum entropy is also calculated for angular momentum algebra when the system is either in a coherent or in an intelligent spin state. These values are compared with the corresponding values of the respective uncertainties. In general, quantum entropies and uncertainties have the same minimum and maximum points. However, for coherent and intelligent spin states, it is found that some minima for the quantum entropy turn out to be uncertainty maxima. We feel that the quantum entropy we use provides the right answer, since it is given in an essentially unique way. Author (revised)

Bohmian mechanics is a deterministic theory of point particles in motion. While avoiding all the paradoxes of nonrelativistic quantum mechanics, it yields the quantum formalism itself--especially the role of self-adjoint operators--as a macroscopic measurement formalism. As an 'application' it is shown that much of the confusion connected with the phase operator for the electromagnetic field arises from a misunderstanding of the role of operators in quantum theory. Avail: CASI HC A02/MF A04

The prescription for introducing a gauge transformation into a quantum transition amplitude, nominally well known, contains an ambiguous feature. It is presumed by some authors that an appropriate transformation of the phase of a wave function will generate the associated gauge transformation. It is shown that this is a necessary but not sufficient step. Examples from the literature are cited to show the consequences of the failure of this procedure. One must distinguish between true gauge transformations and unitary transformations within a fixed gauge. Author

COLLISION-INDUCED SQUEEZING IN A HARMONIC OSCILLATOR c77
Hai-Woong Lee *In* NASA. Goddard Space Flight Center, The Second International Workshop on Squeezed States and Uncertainty Relations 1993 p 291-293 Sponsored in part by Korea Science and Engineering Foundation (For primary document see N94-10564 01-74)
Avail: CASI HC A01/MF A04

The concept of squeezing has so far been applied mainly to light, as is evidenced by the number of research works on the subject of squeezed light. Since, in quantum mechanics, both light and the simple harmonic oscillator are described within the same mathematical framework, there is of course no difficulty in applying the concept to the simple harmonic oscillator as well. In fact, the theoretical development of squeezed states and squeezed light owes much to the physical insights that one obtains as the analogy between light and the harmonic oscillator is exploited. The example presented shows clearly that two states with different phases in general have different degrees of squeezing, even if they have the same state distribution. This means that, even if one considers collision processes that produce the same state distribution, the degree of squeezing obtained during and after the collisions can be quite different, depending on how the phases phi(sub n) of the probability amplitudes develop in time as the collisions proceed. It is therefore evident that, for a detailed study of collision-induced squeezing, further study on the time development of the phases in collisions and its relation to collision parameters such as potential energy surfaces and collision energy is needed. POSITIVE PHASE SPACE DISTRIBUTIONS AND UNCERTAINTY RELATIONS c77
Jan Kruger *In* NASA, Goddard Space Flight Center, The Second International Workshop on Squeezed States and Uncertainty Relations 1993 p 295-300 (For primary document see N94-10564 01-74)
Avail: CASI HC A02/MF A04

In contrast to a widespread belief, Wigner's theorem allows the construction of true joint probabilities in phase space for distributions describing the object system as well as for distributions depending on the measurement apparatus. The fundamental role of Heisenberg's uncertainty relations in Schroedinger form (including correlations) is pointed out for these two possible interpretations of joint probability distributions. Hence, in order that a multivariate normal probability distribution in phase space may correspond to a Wigner distribution of a pure or a mixed state, it is necessary and sufficient that Heisenberg's uncertainty relation in Schroedinger form should be satisfied. The possibility of the formation of squeezed states of gluon fields in quantum chromodynamics due to nonlinear nonperturbative self interaction during jet evolution in the process of e(+)e(-) annihilation into hadrons, which are analogous to the quantum photon squeezed states in quantum electrodynamics, is demonstrated. Additionally, the squeezing parameters are calculated. Author (revised)

NEW SQUEEZED LANDAU STATES c77
C. Aragone *In* NASA. Goddard Space Flight Center, The Second International Workshop on Squeezed States and Uncertainty Relations 1993 p 311-316 (For primary document see N94-10564 01-74)
Avail: CASI HC A02/MF A04

We introduce a new set of squeezed states through the coupled two-mode squeezed operator. It is shown that their behavior is simpler than the correlated coherent states introduced by Dodonov, Kurmyshev, and Man'ko in order to quantum mechanically describe the Landau system, i.e., a planar charged particle in a uniform magnetic field. We compare results for both sets of squeezed states. Author (revised)

THE UNCERTAINTY PRINCIPLE AND QUANTUM CHAOS c77
Boris V. Chirikov *In* NASA. Goddard Space Flight Center, The Second International Workshop on Squeezed States and Uncertainty Relations 1993 p 317-327 (For primary document see N94-10564 01-74)
Avail: CASI HC A03/MF A04

The conception of quantum chaos is described in some detail. The most striking feature of this novel phenomenon is that all the properties of classical dynamical chaos persist here but, typically, on the finite and different time scales only. The ultimate origin of such a universal quantum stability is in the fundamental uncertainty principle which makes discrete the phase space and, hence, the spectrum of bounded quantum motion. Reformulation of the ergodic theory, as a part of the general theory of dynamical systems, is briefly discussed. Author (revised)

Avail: CASI HC A03/MF A04

The general theory of atomic angular momentum states is used to derive the Wigner distribution function for atomic angular momentum number states, coherent states, and squeezed states. These Wigner functions W(theta,phi) are represented as a pseudo-probability distribution in spherical coordinates theta and phi on the surface of a sphere of radius the square root of j(j +1) where j is the total angular momentum. It is shown that the wavelet is the natural language for the Lorentz covariant description of localized light waves. A model for covariant superposition is constructed for light waves with different frequencies. It is therefore possible to construct a wave function for light waves carrying a covariant probability interpretation. It is shown that the time-energy uncertainty relation (Delta(t))(Delta(w)) is approximately 1 for light waves is a Lorentz-invariant relation. The connection between photons and localized light waves is examined critically. Author (revised)

NON-STATIONARY AND NON-LINEAR DISPERSIVE MEDIUM AS EXTERNAL FIELD WHICH GENERATES THE SQUEEZED STATES c77
A. A. Lobashov and V. M. Mostepanenko (Saint Petersburg Technical Univ., Russia.) *In* NASA. Goddard Space Flight Center, The Second International Workshop on Squeezed States and Uncertainty Relations 1993 p 359-362 (For primary document see N94-10564 01-74)
Avail: CASI HC A01/MF A04

The theory of quantum effects in nonlinear dielectric media is developed. The nonlinear dielectric media is influenced by an external pumping field. The diagonalization of the Hamiltonian of a quantized field is obtained by the canonical Bogoliubov transformations. The transformations allow us to obtain the general expressions for the number of created photons and for the degree of squeezing. In the case of a plane pumping wave, for example, the results are calculated by using the zero order of the secular perturbation theory, with small parameters characterizing the medium nonlinearity. The Heisenberg equations of motion are obtained for non-stationary case and a commonly used Hamiltonian is derived from the first principles of quantum electrodynamics. Author (revised)

We show that the probability distributions P(sub n)(q,p;y) := the absolute value squared of (n(p,q;y), which are obtained from squeezed states, obey an interesting partial differential equation, to which we give two intuitive interpretations: as a wave equation in one space dimension; and as a pseudo-diffusion equation. We also study the corresponding Wehrl entropies S(sub n)(y), and we show that they have minima at zero squeezing, y = 0. Author (revised)

Avail: CASI HC A01/MF A04

Nonstationary quantum systems have no energy levels. However, for time-dependent periodical quantum systems, the notion of quasi-energy levels has been introduced. The main point of the quasi-energy concept is to relate quasi-energies to eigenvalues of the Floquet operator or monodromy operators which is equal to the evolution operator of a quantum system taken at the moment coinciding with the period of the system. The purpose of this article is to relate the Floquet operator to integrals of the motion and to introduce a new operator which is the integral of motion and has the same quasi-energy spectrum that the Floquet operator has. We wish to discuss an explicit formula for this new integral of motion. Author (revised)

FABRICATION AND ANALYSIS OF A SPECIAL OPTICAL CONNECTOR CONTAINING A 1/4-INCH-LONG OPTICAL FIBER FOR DOI TESTS
P. E. Klingsporn Apr. 1993 37 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC04-76DP-00613)
(DE93-013115; KCP-613-5039) Avail: CASI HC A03

A technique was developed for fabricating a special optical connector containing an optical fiber of approximately 1/4-inch length for positioning in one end of an adapter to mate with a standard SMA optical connector that terminates a much longer optical fiber. A special holding block was devised for lapping and polishing both ends of the short fibers in four connectors simultaneously. The very short connector was designed to use in experiments at Sandia National Laboratories (SNL) in coupling a high-energy laser beam through the short fiber into the long fiber cable. On the basis of geometrical optics, an analysis was made of the distribution of light energy arriving at the rear face of the short, straight optical fiber segment as a function of the half-angle of a cone of light incident on the front face of the fiber segment. The choice of the operational wavelength for a SXPL system will affect a wide variety of system parameters such as optical design, sources, resists, and multilayer mirrors. Several system constraints limit the choice for the operational wavelength. In particular, optical imaging requirements place an upper limit and throughput issues place a lower limit on the wavelength selection. The authors have determined that there exist several discrete wavelength regions between 10 and 25 nm which satisfy the system imposed constraints of high resolution, large depth of focus, and high throughput. An alkali metal filter having a layer of metallic bismuth deposited onto the alkali metal is provided. The metallic bismuth acts to stabilize the surface of the alkali metal to prevent substantial surface migration from occurring on the alkali metal, which may degrade optical characteristics of the filter. To this end, a layer of metallic bismuth is deposited by vapor deposition over the alkali metal to a depth of approximately 5 to 10 A. A complete alkali metal filter is described along with a method for fabricating the alkali metal filter.

DESIGN AND ANALYSIS OF AN OPTICAL INTERFACE MESSAGE PROCESSOR Final Report, May 1991 - Aug. 1992
Q. W. Song Mar. 1993 160 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F30602-91-C-0048)
(AD-A266079; RL-TR-93-19) Avail: CASI HC A08

Optical technology has become a significant part of communications networks. This effort will design, develop, and experimentally evaluate an optical interface message processor (OPTIMP) that exploits the high bandwidth, parallelism, and high storage density offered by optics. The most time consuming operations such as switching and routing in communications networks will be performed in the optical domain. Because of this, the OPTIMP will not suffer from the electrical - optical/optical - electrical conversion bottlenecks, and therefore, it will perform switching and routing in the gigabits/sec range. CONTINUED DEVELOPMENT OF AN ULTRA-NARROW BANDPASS FILTER FOR SOLAR RESEARCH Final Technical Report
David M. Rust 9 Sep. 1993 17 p
(Grants NAGw-2416; AF-AFOSR-0077-87; AF-AFOSR-0102-90)
(NASA-CR-194169; NAS 1.26:194169) Avail: CASI HC A03/MF A01

The objective of work under this task was to develop ultranarrow optical bandpass filters and related technology necessary for construction of a compact solar telescope capable of operating unattended in space. The scientific problems to which such a telescope could be applied include solar seismology, solar activity monitoring, solar irradiance variations, solar magnetic field evolution, and the location of targets for narrow-field specialized telescopes. We have demonstrated a Y-cut lithium-niobate Fabry-Perot etalon. This filter will be used on the Flare Genesis Experiment. We also obtained solar images with a Z-cut etalon. The technical report on etalon filters is attached to this final report. We believe that work under this grant will lead to the commercial availability of a universal optical filter with approximately 0.1 A bandwidth. Progress was made toward making a suitable 1-2 A tunable blocker filter, but it now appears that the best approach is to make a double-cavity etalon that will not require such a narrow blocker. Broader band blockers are commercially available.

ENHANCED DAMAGE-RESISTANT OPTICS FOR SPACEFLIGHT LASER SYSTEMS: WORKSHOP FINDINGS AND RECOMMENDATIONS
Norman Schulze, Marc Cimolino (Science and Technology Corp., Hampton, VA.), Arthur Guenther (Sandia National Labs., Albuquerque, NM.), Ted McMinn (McDonnell-Douglas Electronic Systems Co., Saint Louis, MO.), Frank Rainer (Lawrence Livermore National Lab., CA.), Ansgar Schmid (Rochester Univ., NY.), Steven C. Seitel (Montana Laser Optics, Inc., Bozeman.), M. J. Soileau (University of Central Florida, Orlando.), John S. Theon, and William Walz (Hughes Danbury Optical Systems, Inc., CT.) 1991 39 p Workshop held in Newport News, VA, 10-12 Sep. 1991
(NASA-TM-109243; NAS 1.15:109243) Avail: CASI HC A03/MF A01

NASA has defined a program to address critical laser-induced damage issues peculiar to its remote sensing systems. The Langley Research Center (LaRC), with input from the Goddard Space Flight Center (GSFC), has developed a program plan focusing on the certification of optical materials for spaceflight applications and the development of techniques to determine the reliability of such materials under extended laser exposures. This plan involves cooperative efforts between NASA and optics manufacturers to quantify the performance of optical materials for NASA systems and to ensure NASA's continued application of the highest quality optics possible for enhanced system reliability. A review panel was organized to assess NASA's optical damage concerns and to evaluate the effectiveness of the LaRC proposed program plan. This panel consisted of experts in the areas of laser-induced damage, optical coating manufacture, and the design and development of laser systems for space. The panel was presented information on NASA's current and planned laser remote sensing programs, laser-induced damage problems already encountered in NASA systems, and the proposed program plan to address these issues. Additionally, technical presentations were made on the state of the art in damage mechanisms, optical materials testing, and issues of coating manufacture germane to laser damage. Derived from text

SMART SPATIAL LIGHT MODULATOR RESEARCH AND DEVELOPMENT Annual Report, 30 Sep. 1992 - 28 Feb. 1993
Sing H. Lee 28 Feb. 1993 30 p
(Contract F49620-92-J-0467)
(AD-A264928; AFOSR-93-0353TR) Avail: CASI HC A03/MF A01

The objective of our research is to demonstrate 'smart' spatial light modulators (S-SLM) where electronic logic circuits are combined with light modulators and detectors. Our previous studies, while providing valuable insights, indicated that shortcomings of certain approaches limit their applicability to combine Si-based driver and logic circuits with PLZT modulators. For example, PLZT substrate damage limited laser recrystallization approach. Lastly, voltage compatibility problem exists that imposes difficulties in the integration of the modulator driver circuit (requiring 30-50V) in the Si-waver containing logic circuits (operating at 5V). In order to resolve these limitations we explored (1) two methods of implementing thin films of Si-band driver circuits directly onto PLZT substrates and (2) flip-chip bonding of Si wafer containing detector and logic circuits onto the silicon bonded directly to bulk PLZT substrate for fabrication of S-SLM. PRESORT PROCESSOR Final Report, Jan. 1989 - Dec. 1991
David Grucza Dec. 1992 22 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AF Proj. 4600)
(AD-A263872; RL-TR-92-338) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Optical notch filtering is a technique utilizing acousto-optics and Fourier Transform Optics to excise bands of frequencies from a radio frequency spectrum. The purpose of the presort processor is to excise strong narrow band signals from a wideband radar return. The intent of this project was to upgrade a processor built for Rome Laboratory by Harris Corporation by upgrading certain components which have been improved in the years since the beginning of the Harris project. This upgrade has not been completed because of delays in the fabrication of new spatial light modulators, the component which actually performs the excision. Because of this delay and other factors outlined in the remainder of this report we have decided to design an entirely new system under a new project. Many of the program goals in this project have not been met, but have been transferred to JON 4600P112. DTIC

SPATIAL LIGHT REBROADCASTER ARCHITECTURE STUDY Final Report, 1 Apr. 1990 - 30 Sep. 1992
J. Cederquist, D. Angell, A. Tai, S. Cartwright, and N. Subotic Dec. 1992 160 p
(Contract F33615-90-C-1437)
(AD-A266102; ERIM-226800-27-F; WL-TR-93-5004) Avail: CASI HC A08/MF A02

There is a need for a processor to perform real-time automatic target classification (ATC) that is compact and consumes little electrical power. Optical processors have the potential to provide the needed computational power in a small package. Substantial efforts have been expended in the development of spatial light modulators (SLMs) to meet the ATC requirements, but performance achieved thus far is still lacking. A new class of optical devices, spatial light rebroadcasters (SLRs) have been developed recently with potential performance far exceeding current SLMs. Instead of modulating the input light field, SLR absorbs the incident radiation and re-emits when triggered to do so. The triggering can be accomplished with an optical signal which also carries spatial information. The storage capability and the relationship between the intensities of the incident (input), triggering (readout) and emitted (output) radiations can be used to perform parallel processing of two-dimensional spatial data. In this report, several optical processing architectures were developed and five of the most promising were analyzed in detail. In addition, preliminary experiments were performed to evaluate the hardware required for two of the architectures. DTIC

IMPLEMENTATION AND USE OF A COMPUTATIONAL RAY-TRACING PROGRAM FOR THE DESIGN AND ANALYSIS OF COMPLEX OPTICAL SYSTEMS M.S. Thesis
James D. Atkinson, IV Mar. 1993 54 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A265075) Avail: CASI HC A04

A new ray-tracing computer program is presented as an analysis and design tool for the development of complex optical systems. The algorithms for the ray-tracing are presented for a wide variety of optical systems surface types. Unique methods for the prediction of two-beam interference patterns are implemented so that amplitude-splitting interferometers can be modeled. Modules for line shape analysis and data storage are also described. This program (DART) is validated using the previously established characteristics of the Middle Ultraviolet Spectral Analysis of Nitrogen Gasses (MUSTANG) instrument, which has a resolution of 10 A, an X-axis field-of-view of 1.2 milliradians, a Y-axis field-of-view of 37 milliradians, and 1600 A bandpass. DART is used to predict the optical characteristics of a new instrument, ISAAC, that is planned for satellite deployment in 1995. The full wavelength range of ISAAC is 1250 A, and the instantaneous band-pass is approximately 250 A. The full wavelength coverage is obtained by rotating a reflection grating in five discreet steps. Based on the DART calculations, the resolution of the ISAAC instrument will exceed 1.30 A for all bands, with resolutions as low as 1.06 A at the longer wavelengths. The predicted X-axis field-of-view is 0.5 milliradians and the Y-axis field-of-view is 36 milliradians. DTIC

(DE93-009515; UCRL-CR-113095) Avail: CASI HC A04/MF A01 (US Sales Only)

The Kestrel LOS Tracking Program involves the development of a computer and algorithms for use in passive tracking of airborne targets from a high altitude balloon platform. The computer receivers track error signals from a video tracker connected to one of the imaging sensors. In addition, an on-board IRU (gyro), accelerometers, a magnetometer, and a two-axis inclinometer provide inputs which are used for initial acquisitions and course and fine tracking. Signals received by the control processor from the video tracker, IRU, accelerometers, magnetometer, and inclinometer are utilized by the control processor to generate drive signals for the payload azimuth drive, the Gimballed Mirror System (GMS), and the Fast Steering Mirror (FSM). The hardware which will be procured under the LOS tracking activity is the Controls Processor (CP), the IRU, and the FSM. The performance specifications for the GMS and the payload canister azimuth driver are established by the LOS tracking design team in an effort to achieve a tracking jitter of less than 3 micro-rad, 1 sigma for one axis. NEW CHALLENGES IN OPTICAL MATERIALS DEVELOPMENT
W. F. Krupke Feb. 1993 9 p Presented at the Symposium on Optical Materials for High-Power Lasers, Boulder, CO, 28-30 Oct. 1992
(Contract W-7405-eng-48)
(DE93-011889; UCRL-JC-113188; CONF-921047-2) Avail: CASI HC A02/MF A01

The recent emergence of high performance semiconductor laser diodes and diode arrays emitting at wavelengths between 630 and 2300 nm has enabled the demonstration of several novel diode-pumped solid state laser materials. Narrowly, laser diode arrays may be viewed as simple replacements for conventional flash or arc lamp pumps in solid state lasers. The examples discussed in this paper illustrate that laser diode array pumps are considerably more versatile, enabling novel high performance lasers that are technically not feasible using conventional flashlamps. Additionally, several relatively new nonlinear optical materials, possessing high nonlinearities and excellent phase-matching properties, offer good prospects for the development of efficient, compact, wavelength-diverse all-solid-state laser sources. THE EVOLUTION OF WHOLE FIELD OPTICAL DIAGNOSTICS FOR EXTERNAL TRANSONIC TESTING
K. A. Fry and P. Bryanston-Cross (Warwick Univ., Coventry, England.) Sep. 1992 15 p Presented at the European Forum on Wind Tunnels and Wind Tunnel Testing Techniques, Southampton, England, 14-17 Sep. 1992
(ARA-Memo-379) Avail: CASI HC A03/MF A01

The diagnostic use of quantitative laser flow visualization techniques has increased rapidly over recent years. The limitations imposed by conventional single point techniques such as laser Doppler anemometry are addressed and how they have been overcome by the development of a new family of whole field measurement techniques is demonstrated. In particular near instantaneous whole field velocity data was obtained in a relatively hostile, industrial 2.74 m x 2.44 m transonic wind tunnel (TWT) at the Aircraft Research Association (ARA). The techniques were evaluated for their suitability for making quantitative measurements in the wing/pylon region of a model wing and engine combination. Three optical diagnostic techniques were successfully developed within the context of the ARA facility. The first technique, laser light sheet (LLS), combines the operation of a pulse laser and video capture system to provide a 'real time' visualization of the flow, whereas a second pulse laser technique, Particle Image Velocimetry (PIV) can be used to make specific quantitative whole field instantaneous velocity measurements. The third method, holography, was used to produce a stored three dimensional visualization of the unsteady and shock wave features of the transonic flow in the gully region. A description is made of their installation and operation, and examples are presented of current test results. Author (revised)

LIGHT SCATTERING FROM A SPHERICAL PARTICLE ON A CONDUCTING PLANE. PART 1: NORMAL INCIDENCE
B. R. Johnson 1 May 1993 52 p
(Contract F04701-88-C-0089)
(AD-A265920; TR-0091(6945-08)-Pt-1; SMC-TR-93-30-Pt-1) Avail: CASI HC A04/MF A01

A new procedure is developed for calculating light scattering from a spherical particle on a conducting plane. The discussion is limited to problems in which the incident light beam is perpendicular to the plane. A general proof is given for the method of images, which is used to convert the problem of a particle on a conducting plane to an equivalent two-particle problem. The scattering solution for the two-particle is then obtained by the multipole expansion method. Mirror symmetry is exploited to simplify the calculation. Formulas are developed for the extinction and absorption cross sections. Several example problems are calculated, and the exact solutions are compared to the results from two commonly used approximation procedures. DTIC

LIMITATIONS TO THE QUALITY OF OPTICAL PHASE CONJUGATION BY STIMULATED BRILLOUIN SCATTERING Ph.D. Thesis
Thomas R. Moore 1993 138 p
(AD-A266006) Avail: CASI HC A07/MF A02

The process of optical phase conjugation by stimulated Brillouin scattering is studied both theoretically and experimentally, with emphasis on aspects that apply to phase-conjugate lasers. A theoretical formalism based on decomposing the optical field into a set of orthogonal modes is presented; this formalism is then used as the basis for numerical modeling. Many of the steady-state aspects of stimulated Brillouin scattering are investigated including the following: the distribution of energy in the interaction region, the spatial effects of distributed noise, phase pulling of the Strokes wave, and the affects of adding smooth aberrations to the pump beam. A new design for a robust, inexpensive, solid-state, phase-conjugate laser is also presented. DTIC

ASYNCHRONOUS TRANSFER MODE (ATM) TECHNOLOGY: AN OVERVIEW Final Report
James R. Webster 4 Jun. 1993 23 p
(AD-A266087; NRL/MR/8143-93-7337) Avail: CASI HC A03/MF A01

This paper presents a brief overview of the emerging network protocol standard known as Asynchronous Transfer Mode or ATM. ATM was developed by the telecommunications industry as part of the long-term shift of communications services to the B-ISDN standard. By taking advantage of the highly reliable fiber optic networks available, ATM offers faster and more efficient data communications than existing protocols such as X.25. A rigorous, layered protocol exists that gives ATM the flexibility to carry many different types of traffic, including voice, imagery, and video, as well as data. DTIC

PRELIMINARY SURFACE-EMITTING LASER LOGIC DEVICE EVALUATION Final Report, Oct. 1991 - Sep. 1992
S. I. Libby, M. A. Parker, G. R. Olbright, and P. D. Swanson Mar. 1993 18 p
(AD-A266111; RL-TR-93-35) Avail: CASI HC A03/MF A01

This report discusses the evaluation of a monolithically integrated heterojunction phototransistor and vertical-cavity surface-emitting laser, designated the surface-Emitting Laser Logic device (CELL). Included is a discussion of the device structure and theory of operation, test procedures, results, and conclusions. Also presented is the CELL's opto-electronic input/output characteristics which includes spectral analysis, characteristic emitted light versus current and current versus voltage curves, input wavelength tolerance, output wavelength sensitivity to bias current, and insensitivity to input wavelength and power within a specified range. OPTOELECTRONIC TECHNOLOGY CONSORTIUM Quarterly Technical Report No. 3, 1 Jan. - 1 Mar. 1993
Mary Hibbs-Brenner 12 May 1993 11 p
(Contract MDA972-92-C-0071)
(AD-A265691) Avail: CASI HC A03/MF A01

The Optoelectronic Technology Consortium has been established to position U.S. industry as the world leader in optical interconnect technology by developing, fabricating, integrating, and demonstrating the producibility of optoelectronic components for high-density/high-data-rate processors and accelerating the insertion of this technology into military and commercial applications. This objective will be accomplished by a program focused in three areas: (1) demonstrated performance--OETC will demonstrate an aggregate data transfer rate of 16 Gb/s between single transmitter and receiver packages, as well as the expandability of this technology by combining four links in parallel to achieve a 64 Gb/s link; (2) accelerated development--by collaborating during the precompetitive technology development stage, OETC will advance the development of optical components and produce links for a multiboard processor testbed demonstration; and (3) producibility--OETC's technology will achieve this performance by using components that are affordable, and reliable, with a line BER less than 10(exp -15) and MTTF greater than 10(exp 6). EFFICIENCY OF FAST WAVE CURRENT DRIVE FOR A WEAKLY RELATIVISTIC PLASMA
S. C. Chiu, Y. R. Lin-Liu, and C. F. F. Karney (Princeton Univ., NJ.) Apr. 1993 4 p Presented at the 10th Topical Conference on Radio Frequency Power in Plasmas, Boston, MA, 1-3 Apr. 1993
(Contracts DE-AC03-89ER-51114; DE-AC02-76CH-03073)
(DE93-012775; GA-A-21254; CONF-9304112-4) Avail: CASI HC A01/MF A01

Current drive by fast waves (FWCD) is an important candidate for steady-state operation of tokamaks. Major experiments using this scheme are being carried out on D3-D. There has been considerable study of the theoretical efficiency of FWCD. In other research, the nonrelativistic efficiency of FWCD at arbitrary frequencies was studied. For D3-D parameters, the results can be considerably different from the Landau and Alfven limits. At the high temperatures of reactors and D3-D upgrade, relativistic effects become important. In this paper, the relativistic FWCD efficiency for arbitrary frequencies is studied. Assuming that the plasma is weakly relativistic, i.e., T(sub e)/Mc(exp 2) is small, an analytic expression for FWCD is obtained for high resonant energies (u(sub ph)/u(sub Te)(much greater than 1)). Comparisons with the results from a numerical code ADJ and the nonrelativistic results shall be made and analytical fits in the whole range of velocities shall be presented. DOE

SIMULATIONS OF D3-D DIVERTOR BIASING WITH THE LEDGE CODE
M. E. Rensink, J. Milovich, and T. Rognlien Sep. 1992 15 p Presented at the IAEA Technical Committee Meeting on Tokamak Plasma Biasing, Montreal, Ottawa, 8-10 Sep. 1992
(Contract W-7405-eng-48)
(DE93-010500; UCRL-JC-110-843; CONF-9209181-7) Avail: CASI HC A03/MF A01

We use the LEDGE 2D fluid model to determine the effects of electrically biasing the outboard divertor plate in D3-D. The LEDGE code includes classical perpendicular and parallel current flows as well as E x B and diamagnetic drifts. Boundary conditions at the divertor plates allow the sheath parameters to vary with current flow across the sheath. Ohmic heating and convective heat flow associated with the current flow are included. Neutrals originating at the divertor plates due to recycling are represented by a fluid model. We explore the effect of cross-field drifts and variations in the bias voltage. The current-voltage characteristic, inboard/outboard heat flux asymmetry, and radial plasma profiles are computed. We show that cross-field drifts have a strong effect on the plasma profiles at the diverter plates. Differential biasing of the inboard and outboard divertor plates can significantly modify the naturally occurring outboard/inboard heat flux asymmetry, but it only weakly affects radial profiles at the outboard plate. X RAY PRODUCTION (APPROXIMATELY)130 (ANGSTROM) FROM LASER-PRODUCED PLASMAS FOR PROJECTION X RAY LITHOGRAPHY APPLICATIONS
R. L. Kauffman, D. W. Phillion, and R. C. Spitzer 30 May 1992 14 p Presented at the Soft X Ray Projection Lithography Topical Meeting, Monterey, CA, 6-8 Apr. 1992
(Contract W-7405-eng-48)
(DE93-009256; UCRL-JC-110217; CONF-9204120-5) Avail: CASI HC A03/MF A01

X-ray production in the region around 130 A from laser-produced plasmas have been investigated as a source for projection x-ray lithography. The dependence of x-ray conversion efficiency on target material, intensity, and pulse length has been studied using a 0.53 micron laser with a maximum of 0.3 J. Conversion efficiency of 1% into a 3 A bandwidth has been demonstrated for Sn targets at intensities around 10(exp 11) W/sq cm using a 7.5 ns pulse. Intensity scaling suggests that laser spot size and two-dimensional expansion are important for optimizing x-ray production at these low irradiation intensities. DOE

TRANSPORT MECHANISMS ACTING IN TOROIDAL DEVICES: A THEORETICIAN'S VIEW
B. A. Carreras Jan. 1993 26 p
(Contract DE-AC05-84OR-21400)
(DE93-013463; ORNL/TM-12209) Avail: CASI HC A03/MF A01

Understanding the basic mechanisms of transport in toroidal confinement devices remains one of the more challenging scientific issues in magnetic confinement. At the same time, it is a critical issue for the magnetic fusion program. Recent progress in understanding fluctuations and transport has been fostered by the development and use of new diagnostics, bringing new perspectives on these studies. This has stimulated new theoretical developments. A view of the most recent issues and progress in this area is given. The role of long wavelengths in core transport and the relation between shear flows and turbulence at the plasma edge are the primary topics considered. DOE

TEXAS EXPERIMENTAL TOKAMAK
A. J. Wootton Apr. 1993 89 p
(Contract DE-FG05-88ER-53267)
(DE93-013377; DOE/ER-53267/6) Avail: CASI HC A05/MF A01

This progress report covers the period from November 1, 1990 to April 30, 1993. During that period, TEXT was operated as a circular tokamak with a material limiter. It was devoted to the study of basic plasma physics, in particular to the study of fluctuations, turbulence, and transport. The purpose is to operate and maintain TEXT Upgrade as a complete facility for applied tokamak physics, specifically to conduct a research program under the following main headings: (1) to elucidate the mechanisms of working gas, impurity, and thermal transport in tokamaks, in particular to understand the role of turbulence; (2) to study physics of the edge plasma, in particular the turbulence; (3) to study the physics or resonant magnetic fields (ergodic magnetic divertors, intra island pumping); and (4) to study the physics of electron cyclotron heating (ECRH). Results of studies in each of these areas are reported. DOE

AN INVESTIGATION OF CONDUCTED AND RADIATED EMISSIONS FROM A HOLLOW-CATHODE PLASMA CONTACTOR Annual Report, 1 Jan. 1992 - 1 Jan. 1993
Brett W. Buchholtz and Paul J. Wilbur Jul. 1993 99 p
(Grant NAG3-776)
(NASA-CR-191172; NAS 1.26:191172) Avail: CASI HC A05/MF A02

An investigation conducted on the electrical interference induced by the operation of a hollow-cathode plasma contractor in a ground-based facility is described. The types of electrical interference, or noise, which are important to Space Station Freedom designers are classified as either conducted or radiated emissions. The procedures required to perform conducted and radiated emission measurements on a plasma contactor are examined. The experimental data obtained are typically examined in the frequency domain (i.e. amplitudes of the noise fluctuations versus frequency). Results presented indicate the conducted emissions, which are the current fluctuations from the contactor into the space station wiring, are affected by operating parameters such as expellant flow rate and discharge current. The radiated emissions, which are the electromagnetic waves induced and emitted by the contactor, appear to be influenced by the contactor emission current. Other experimental results suggest possible sources which are responsible for the observed noise. For example, the influence of the plasma environment downstream from the contactor on noise emission levels is described. In addition, a brief discussion is given on the correlation between conducted and radiated emissions and the mechanisms through which both are influenced by the plasma downstream of the contactor. NONLINEAR SECOND HARMONIC GENERATION BY LIGHT WAVE-PLASMA INTERACTION IN OSCILLATING MAGNETIC FIELD
S. M. Khalil, B. F. Mohamed, and F. Sharaf Sep. 1992 7 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-613723; IC-92/290) Avail: CASI HC A02 (US Sales Only)

The nonlinear generation of second harmonic electromagnetic waves in a thin inhomogeneous (dense and rarefied) plasma layer (of length d) by obliquely and normally incident light waves is analyzed. We consider the effect of external time-dependent magnetic fields on the generation and amplification of waves. Two cases are considered: (1) the first case is when the magnetic field oscillates at a frequency equal to that of the incident wave; and (2) the second is when the magnetic field oscillates at a frequency that is double that of the incident wave. For normal incidence, waves are not radiated in the first case, while in the second case, the second harmonics are radiated equally from the plasma boundaries at $x = 0$ and $x = d$. For rarefied plasma, the second harmonics are radiated with equal amplitudes in both cases. DOE

OPTIMIZATION OF BREAK-DOWN CONDITIONS IN TOKAMAK TOTUS [OPTIMIZATSIYA USLOVIJ PROBOYA V TOKAMAKE TOTUS]
V. B. Vidzigovskij, A. A. Gurin, and V. I. Nedovba et al 1991 19 p In RUSSIAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-617863; KIYaI-91-15) Avail: CASI HC A03 (US Sales Only)

The results are given for first experiments on tokamak TOTUS, intended for research of problems of control by discharges and plasmas characteristics. The essential peculiarity of the device is the hybrid poloidal magnetic system, combining the functions of air inductor, control windings, and windings forming the plasma cross-section configuration. As the result of investigations the break-down conditions were established. It has created the multi-sectional programmed supply system of the poloidal winds for discharge plus start phase and its operating algorithm. The main parameters of device systems were optimized for break-down phase. DOE

STATIONARY SPECTRA IN A FINITE-PRESSURE CURRENT-CARRYING PLASMA

M. O. Vakulenko 1992 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-617848; ITP-92-24) Avail: CASI HC A03 (US Sales Only)

The short-wave (wavelengths smaller than the ion gyroradius) low-frequency (frequencies less than the ion gyrofrequency) potential, cross, and magnetic stationary fluctuation spectra are found in a finite pressure current-carrying plasma on the basis of canonical distribution, a renormalized statistical approach with cross-field correlations, and a self-similar analysis. DOE

N94-10539 Academy of Sciences of the Ukraine, Kiev. Inst. Teoreticheskoj Fiziki.

STATIONARY SPECTRA IN A QUASI NEUTRAL CURRENT-CARRYING PLASMA

M. O. Vakulenko 1992 10 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-617849; ITP-92-25) Avail: CASI HC A02 (US Sales Only)

The low-frequency short-wave equilibrium spectra of electromagnetic fluctuations are obtained. In doing so, we account for the cross-field correlations. Statistical analysis shows that a longitudinal current in a dense quasi-neutral (alpha(sub e) = 4(pi)n(sub 0)m(sub e)c(exp 2)/beta(sub 0)(exp 2) is much greater than 1) plasma destroys the stationary of fluctuation spectra corresponding to zero fluxes of motion invariants, and it may also alter the anomalous electron heat conductivity. DOE

N94-10540 Academy of Sciences of the Ukraine, Kiev. Inst. Teoreticheskoj Fiziki.

STATIONARY SPECTRA IN A SHEARED PLASMA (LINEAR LIMIT)

M. O. Vakulenko 1992 10 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-617850; ITP-92-26) Avail: CASI HC A02 (US Sales Only)

The short-wave low-frequency stationary spectra of correlated electromagnetic fluctuations in a sheared current-currying plasma are obtained by a linear approximation. Even being weak, the shear may considerably alter the spectral characteristics of plasma perturbations. DOE

COMPARISON OF HYDRODYNAMIC AND SEMI-KINETIC TREATMENTS FOR PLASMA FLOW ALONG CLOSED FIELD LINES

Nagendra Singh, G. R. Wilson, and J. L. Horwitz 2 Jul. 1993 47 p
(Grant NAGw-2128)
(NASA-CR-193589; NAS 1.26:193589) Avail: CASI HC A03/MF A01

Hydrodynamic and semi-kinetic treatments of plasma flow along closed geomagnetic field lines are compared. The hydrodynamic treatment is based on a simplified 16-moment set of transport equations as the equations for the heat flows are not solved; the heat flows are treated heuristically. The semi-kinetic treatment is based on a particle code. The comparison deals with the distributions of the plasma density, flow velocity, and parallel and perpendicular temperatures as obtained from the two treatments during the various stages of the flow. In the kinetic treatment, the appropriate boundary condition is the prescription of the velocity distribution functions for the particles entering the flux tubes at the ionospheric boundaries; those particles leaving the system are determined by the processes occurring in the flux tube. The prescribed distributions are half-Maxwellian with temperature T(sub 0) and density n(sub 0). In the hydrodynamic model, the prescribed boundary conditions are on density (n(sub 0)), flow velocity (V(sub 0)) and temperature (T(sub 0). It was found that results from the hydrodynamic treatment critically depend on V(sub 0); for early stages of the flow this treatment yields results in good agreement with those from the kinetic treatment, when V(sub 0) = square root of (kT(sub 0)/2 (pi)m), which is the average velocity of particles moving in a given direction for a Maxwellian distribution. During this early stage, the flows developing form the conjugate ionospheres show some distinct transitions. For the first hour or so, the flows are highly supersonic and penetrate deep into the opposite hemispheres, and both hydrodynamics and kinetic treatments yield almost similar features. It is found that during this period heatflow effects are negligibly small. When a flow penetrates deep into the opposite hemisphere, the kinetic treatment predicts reflection and setting up of counterstreaming. In contrast, the hydrodynamic treatment yields a shock in the flow. The reasons for this difference in the two treatments is discussed, showing that in view of the relatively warm ions, the coupling of ion beams and the consequent shock formation in the offequatorial region are not likely due to the enhancements in the beam temperatures. The counterstreaming in the kinetic treatment and the shock in the hydrodynamic treatment first advance upward to the equator and then downward to the ionospheric boundary from where the flow originated. The transit time for this advancement is found to be about 1 hour for the respective models. After 2 hours or so, both models predict that the flows from the ionospheric boundaries are generally subsonic with respect to the local ion-sound speed. At late stages of the flow, when a substantial fraction of ions entering the flux tube begin to return back in the kinetic treatment, the hydrodynamic treatment with the boundary condition V(sub 0) = square root of (kT(sub 0)/2(pi)m) yields an over-refilling, and the choice of V(sub 0) becomes uncertain. Author (revised)

HIGH-FIELD CONDUCTOR TESTING AT THE FENIX FACILITY

S. S. Shen, M. R. Chaplin, B. Felker, W. V. Hassenzahl, K. I. Kishiyama, and J. M. Parker Apr. 1993 6 p Presented at the 8th United States-Japan Workshop on High-Field Superconductors Applied Superconducting Center, Madison, WI, 16-19 Mar. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE93-012318; UCRL-JC-113199; CONF-9303157-1) Avail: Issuing Activity (Department of Energy (DOE))

The Fusion Engineering International experiments (FENIX) Test Facility, which was commissioned at the end of 1991, is the first facility in the world capable of testing prototype conductors for the International Thermonuclear Experimental Reactor (ITER) superconducting magnets. The FENIX facility provides test conditions that simulate the ITER magnet operating environment; more importantly, it also accommodates specific experiments to determine the operational margins for the prototype conductors. The FENIX facility generates magnetic fields close to 14 T, and transport currents over 40 kA for testing the prototype conductors. This paper describes an experimental program that measures critical currents, current-sharing temperatures, forced-flow properties, and cyclic effects. DOE

LOOKING BEYOND ITER: TOROIDAL CONCEPT IMPROVEMENT
J. Sheffield 1993 6 p Presented at the Fusion Power Associates Annual Meeting, La Jolla, CA, 28-29 Jan. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC05-84OR-21400)
(DE93-012762; CONF-9301106-1) Avail: CASI HC A02

The International Thermonuclear Experimental Reactor (ITER) will demonstrate ignition and undertake fusion reactor systems integration and testing. Its design will be based upon relatively conservative physics assumptions. More attractive reactor configurations than those based upon ITER physics and the ITER configuration appear possible. The Toroidal Physics Experiment (TPX) will study tokamak behavior under a variety of conditions which may allow operation of improved combinations of beta, transport, and recirculating power. However, TPX still retains a configuration similar to ITER. Two alternative approaches appear interesting, based upon recent experimental results: the very low aspect ratio tokamak, or spherical torus, and the stellarator. DOE

REVERSED-FIELD PINCH STUDIES IN THE MADISON SYMMETRIC TORUS
S. Hokin, A. Almagri, M. Cekic, B. Chapman, N. Crocker, D. J. DenHartog, G. Fiksel, J. Henry, H. Ji, and S. Prager et al 3 Apr. 1993 18 p
(Contract DE-FG02-85ER-53198)
(DE93-013464; DOE/ER-53198/218) Avail: CASI HC A03/MF A01

Studies of large-size (R = 1.5 m, a = 0.5 m), moderate current (I less than 750 kA), reversed-field pinch (RFP) plasmas are carried out in the Madison Symmetric Torus in order to evaluate and improve RFP confinement, study general toroidal plasma MHD issues, determine the mechanism of the RFP dynamo, and measure fluctuation-induced transport and anomalous ion heating. MST confinement has been improved by reduction of magnetic field errors with correction coils in the primary circuit and reduction of impurities using boronization; high densities have been achieved with hydrogen pellet injection. MHD tearing modes with poloidal mode number m = 1 and toroidal mode numbers n = 5-7 are prevalent and nonlinearly couple to produce sudden relaxations akin to tokamak sawteeth. Edge fluctuation-induced transport has been measured with a variety of insertable probes. Ions exhibit anomalous heating, with increases of ion temperature occuring during strong MHD relaxation. The RFP dynamo has been studied with attention to various possible mechanisms, including motion-EMF drive, the Hall effect, and superthermal electrons. Initial profile control experiments have begun using insertable biased probes and plasma guns. The toroidal field capacity of MST will be upgraded during Summer, 1993 to allow low-current tokamak operation as well as improved RFP operation. DOE

KINETIC APPROACH TO LONG WAVE LENGTH MODES IN ROTATING PLASMAS
T. Yamagishi (Fukui Inst. of Tech., Japan.) Mar. 1992 42 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-771286; NIFS-138) Avail: CASI HC A03

Stability of low frequency, long wave length modes is studied by a kinetic approach in rotating Maxwellian plasmas. In the rigid rotator model, the centrifugal force due to the plasma rotation strongly destabilizes the ballooning modes, particularly when the Mach number is close to unity. The fluid flow shear weakly stabilizes the ballooning mode. Energetic particles effectively stabilize the ballooning mode, particularly in the high-(beta) region, even in rotating plasmas. The electric potential induced from the radial electric field increases the particle trapping rate for e(sub phi) greater than 0. For phi less than 0, as in tokamaks, the electron trapping rate increases. This destabilizes the dissipative trapped electron mode. DOE

STATIONARY SPECTRA OF SHORT-WAVE CONVECTIVE AND MAGNETOSTATIC FLUCTUATIONS IN A FINITE-PRESSURE PLASMA AND ANOMALOUS HEAT CONDUCTIVITY
M. O. Vakulenko 1992 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-617852; ITP-92-30) Avail: CASI HC A03 (US Sales Only)

Within the general renormalized statistical approach, the low-frequency short-wave stationary spectra of potential and magnetic perturbations in a finite-pressure plasma are obtained. Anomalous heat conductivity considerably enhances due to non-linear interaction between magnetic excitations. DOE

N94-10852# Wisconsin Univ., Madison. Plasma Physics Research.
MAGNETOHYDRODYNAMIC COMPUTATION OF FEEDBACK STABILIZATION OF RESISTIVE-SHELL INSTABILITIES IN THE REVERSED FIELD PINCH Ph.D. Thesis
E. J. Zita 1993 68 p
(Contract DE-FG02-85ER-53212)
(DE93-013466; DOE/ER-53212/212) Avail: CASI HC A04/MF A01

MHD computations demonstrate that feedback can sustain reversal and reduce loop voltage in resistive-shell reversed field pinch (RFP) plasmas. In the absence of a close-fitting conducting shell, feedback with conducting coils on approximately 2R/a tearing modes resonant near axis is found to restore plasma parameters to nearly their levels with a close-fitting conducting shell. When original dynamo modes are stabilized, neighboring tearing modes grow to maintain the RFP dynamo more efficiently. This suggests that experimentally observed limits on RFP pulselengths to the order of the shell time can be overcome by applying feedback to a few helical modes. Feedback with resistive coils yields information on requirements for more physically realistic feedback systems and on the potentiality of improvement of resistive-shell plasma parameters beyond the conducting-shell case. Plasma response to shell rotation is investigated, and issues relevant to mode locking and feedback rotation of individual modes are discussed. DOE

POSSIBILITIES OF MAGNETIC DIAGNOSTICS IN STELLARATORS [VOZMOZHNOSTI MAGNITNOJ DIAGNOSTIKI V STELLARATORAKH]

V. K. Pashnev 1991 19 p In RUSSIAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-621608; KFTI-91-35) Avail: CASI HC A03 (US Sales Only)

Magnetic diagnostic methods can be used successfully in tokamaks, but a direct application of these methods in stellarators gives little effect. However, an additional measuring of magnetic fields in the helical plasma current allows us to obtain information about the limit parameters of magnetic configuration and additional integral relations compared with tokamaks. Measurements of plasma current magnetic fields outside of the plasma confinement volume in stellarators allow us to determine the profiles of important plasma parameters and the magnetic configuration. DOE

CHARGED PARTICLE MOTION IN TORSATRONS, PART 1

M. S. Smirnova and A. A. Shishkin 1991 16 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-621639; KFTI-91-23-Pt-1) Avail: CASI HC A03 (US Sales Only)

The motion of collisionless particles and their confinement conditions in l = 2 torsatrons are analyzed. The considered devices were similar to real torsatron configurations such as Uragan-2M, ATF, and Heliotron E which differ in the number of helical field periods (M), ripple amplitude ratio (E(sub t)/E(sub l)), and in the spectrum of the helical magnetic field. The influence of the different compositions of the spectrum on the particle confinement was considered. DOE

N94-11120 Gosudarstvennyi Komitet po Ispolzovaniyu Atomnoi Energii, Moscow (USSR).
PARTICLE TRANSPORT ANALYSIS IN TORSATRON CONFIGURATIONS
M. S. Smirnova 1991 23 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-621640; KFTI-91-24) Avail: CASI HC A03 (US Sales Only)

The paper analyzes the transport and loss of particles in $l = 2$ torsatrons in the absence of the electric field. The parameters of the devices considered are similar to the real torsatron configurations of Uragan-2M and Heliotron E. The parameters differ in the number of helical field periods over the device length (M), in the ripple amplitude ratio (E(sub t)/E(sub l)), and the harmonic spectrum of the helical magnetic field. Numerical simulation of particle motion, taking the collisions into consideration, is performed by a Monte-Carlo method. The optimum criterion of the helical magnetic field harmonic spectrum from the point of view of particle confinement and transport in plasma is formulated. DOE

PROBABILITY OF PARTICLE TRAPPING/DETRAPPING IN TORSATRONS
I. N. Sidorenko 1991 25 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-621641; KFTI-91-36) Avail: CASI HC A03 (US Sales Only)

By applying Kruskal's theorem, the analytical formulas of collisionless transition probability between classes of locally passing particles and helical trapped particles in magnetic configurations with complicated harmonic spectrum and radial electric field accounting have been obtained. Based on this analytical consideration, the conclusions were made about the fraction of trapped particles in the URAGAN-2M, ATF-1, HELIOTRON-E, and CHS configurations. The electric field potential at which this fraction is a minimum is also obtained. DOE

N94-11125# Lawrence Livermore National Lab., CA.
PHYSICS OF TOKAMAK SCRAPE-OFF LAYER CONFINEMENT
R. H. Cohen Mar. 1993 8 p Presented at the International Topical Conference on New Ideas in Tokamak Confinement, La Jolla, CA, 27-29 Jan. 1992
(Contract W-7405-eng-48)
(DE93-011949; UCRL-JC-109333; CONF-920142-4) Avail: CASI HC A02/MF A01

Confinement in the scrape-off layer (SOL) of a tokamak is believed to be governed by classical flows along magnetic field lines terminated by sheaths, and turbulent transport across field lines. In this paper, we review how these two effects conspire to establish the width of the SOL, and survey recent and ongoing work on mechanisms for turbulence in SOL's. The beneficial relationship between scrape-off layer turbulence in mitigating the heat flux density on divertors is noted, and tactics for actively altering SOL confinement so as to reduce the heat flux density are discussed. SIMULATION STUDY OF DYNAMO STRUCTURE IN REVERSED FIELD PINCH
A. Nagata (Osaka Inst. of Tech., Japan.), K. I. Sato, H. Ashida (Electrotechnical Lab., Ibaraki, Japan.), and T. Amano (National Inst. for Fusion Science, Nagoya, Japan.) Oct. 1992 23 p
(DE93-771406; PSC-24) Avail: CASI HC A03/MF A01

The dynamo structure in the reversed field pinch (RFP) is studied through the nonlinear dynamics of the single-helicity mode. Simulation is concentrated upon the physical structure of nonlinear interactions of the plasma flow and magnetic fluctuation. The result indicates that when the initial equilibrium profile is deformed by resistive diffusion, the radial flow is driven near the core of the plasma. As this flow forms a vortex structure and the magnetic fluctuation grows radially, the dynamo electric field is spirally induced just inside the reversal surface, and then, the toroidal flux is increased. This dynamo electric field correlates to nonlinear evolution of the kinetic energy of $m=1$ mode, and the increase of the toroidal flux is originated in the growth process of the magnetic energy of this mode. Consequently, the RFP configuration can be sustained by the single-helicity evolution of $m=1$ mode alone, and the electric field induced by the interactions of the toroidal velocity and the radial magnetic field is the most dominant source on the dynamo action. GYROSHEATH NEAR THE TOKAMAK EDGE
R. D. Hazeltine, H. Xiao, and P. M. Valanju Mar. 1993 14 p
(Contract DE-FG05-80ET-53088)
(DE93-012191; DOE/ET-53088/599) Avail: CASI HC A03/MF A01

A new model for the structure of the radial electric field profile in the edge during the H-mode is proposed. Charge separation caused by the difference between electron and ion gyromotion, or more importantly in a tokamak, the banana motion (halo effect) can self-consistently produce an electric dipole moment that causes the sheared radial electric field. The calculated results based on the model are consistent with D-3D and TEXTOR experimental results. DOE

STUDIES ON THE PARAMETRIC DECAY OF WAVES IN FUSION PLASMAS Ph.D. Thesis
T. Paettikangas Aug. 1992 166 p Prepared in cooperation with Helsinki Univ. of Technology, Otaniemi, Finland
(DE93-621659; VTT-PUB-110; ISBN-951-38-4228-2) Avail: CASI HC A08

Parametric instabilities of large-amplitude electromagnetic waves are investigated in fusion applications. In laser fusion, the electromagnetic wave reflected from the overdense plasma can act as a secondary pump wave and exite parametric instabilities. In double simulated Brilloun scattering (DSBS), both the incoming and the reflected pump wave scatter from a common ion sound wave. The stationary states and the dynamics of DSBS are investigated by using a simple envelope model. The ion sound wave that is exited in DSBS is shown to have soliton-like properties. The simulated Raman scattering (SRS) of free-electron-laser radiation can be applied to current drive in tokamaks. SRS generates fast longitudinal electron plasma waves which accelerate electrons to relativistic energies. Since the energetic current-carrying electrons are almost collisionless, the current decays very slowly. The feasibility of the Raman current drive in tokamaks is investigated theoretically. The current drive efficiency and the optimum free-electron-laser parameters are determined. The energy transfer to the fast electrons from the electrostatic wave is studied with relativistic Vlasov-Maxwell simulations. The parametric decay of a wave to half-harmonics is investigated. It is shown that the growth rate of the decay vanishes in the limit of a long wavelength of the pump wave even for general electromagnetic or electrostatic decay models. The results are applied to the decay of a fast magnetosonic waves in tokamak plasmas. DOE

MOMENTUM AND HEAT FRICTIONS BETWEEN FAST IONS AND THERMAL PLASMA SPECIES
Jianping Wang, Masafumi Azumi, Keiji Tani, and J. D. Callen (Wisconsin Univ., Madison.) Jun. 1992 29 p
(DE93-771240; JAERI-M-92-087) Avail: CASI HC A03/MF A01

Momentum and heat friction forces between fast ions (isotropic to the lowest order) and thermal bulk plasma species (near Maxwellian) have been derived analytically for the first time using the linearized Fokker-Planck collision operator. Therefore effects of flow-type distortion of test particles and flow-type restoring from field particles are both retained self-consistently. w(sub (alpha)) (identical to) v-V(sub (alpha)) represents the random velocity measured in moving reference frame of test particles, and the superscript (alpha)/(beta) denotes test particles of (alpha) species colliding with field particles of (beta) species. The momentum and heat friction forces have been explicitly calculated for electron-fast ion collisions (F(sub K)(sup e/f)), fast ion-electron collisions (F(sub K)(sup f/e)), thermal ion-fast ion collisions (F(sub K)(sup i/f)) and fast ion-thermal ion collisions (F(sub K)(sup f/i)) wherein the subscripts k's correspond to the indices of Laguerre polynomials ($k = 0, 1$). The collisional moment matrix is shown asymmetric in the presence of fast ions because the approximate self-adjointness of the Coulomb collision operator is no longer a valid property. (author). DOE

EXPERIMENTAL APPROACH TO THE PHYSICS OF THE HIGH DENSITY DIVERTOR
I. H. Hutchinson Mar. 1993 11 p
(Contract DE-AC02-78ET-51013)
(DE93-009149; DOE/FTR-93009149) Avail: CASI HC A03/MF A01 (US Sales Only)

The workshop was held from 25th to 27th February at the ITER co-center at Garching. The agenda is attached. Initial discussions focussed on the direction of the meeting. Parker expressed a hope that physics would emerge. Rebut outlined 3 elements of an approach to solving the divertor problem: (1) work on existing tokamaks; (2) code modelling; and (3) a simulator. Rebut wants to progress rapidly to identify a plan or agreement on work package(s) focused on ITER. Credit would be decided on a case-by-case basis. In answer to Parker's question whether a new specific divertor on an existing machine could receive credit, Rebut said, maybe. His view is that 20-30 million dollars is being spent on a coil testing facility and a roughly similar amount could be spent on divertor testing. It emerged later that Rebut's conception is that this would be a (single probably) facility designed to achieve dimensional equality (as far as possible) with ITER. DOE

KINETIC EFFECTS IN STOCHASTIC TOPOLOGICALLY NONTRIVIAL FIELD
A. V. Chechkin, A. V. Tur, and V. V. Yanovskij 1992 31 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-621642; KFTI-92-25) Avail: CASI HC A03 (US Sales Only)

The kinetic description of a particle system in an external, stochastic, helical field is examined. The kinetic equation is obtained, which contains an additional term proportional to the helicity. A solution that describes the evolution of the distribution function for arbitrary initial conditions is found. Particular examples of such an evolution and some new kinetic effects, connected with helicity, are discussed. It is shown that a particle beam with inhomogeneous velocity profile in an external stochastic helical field generates a new particle flow in the transverse direction. DOE

(DE93-621655; KFTI-91-45) Avail: CASI HC A03 (US Sales Only)

Experimental results of wake field excitation in plasma and in gas by a periodic succession of short relativistic particle clots obtained with the help of a resonance linear accelerator are presented. Electron energy is 2 MeV, clot duration is 60 ps, and the number of particles in a clot is 2 x 10(exp 9). The density of plasma used in experiments provides a resonance between plasma frequency and clot succession frequency. In this case the modulated beam-plasma interaction is represented by a sum of wake fields depending on the number of clots and accompanied by interference and stochastic effects. DOE

NEGATIVE VISCOSITY AND GENERATION OF DISSIPATIVE SOLITONS AND ZONAL DISSIPATIVE STRUCTURES BY DRIFT WAVES

A. V. Chechkin, A. V. Tur, and V. V. Yanovskij 1991 35 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(DE93-621656; KFTI-91-50) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

The stability of drift waves in a plasma with dissipation due to ion viscosity is examined. If the wave amplitude exceeds a threshold value, determined by ion-ion collisions, large-scale perturbations (i.e., with scales much greater than the drift wave length) grow. This effect is analogous to the negative viscosity effect in hydrodynamics. Maximum growth rate belongs to perturbations which are periodical along plasma inhomogeneity and constant in the transverse direction, i.e. azimuthal direction in cylindrical geometry (zonal dissipative structures). The analysis of the nonlinear stage of large-scale instability shows that the soliton-like large-scale structures of the electric field and vorticity are possible (dissipative solitons). DOE

(DE93-621658; KFTI-92-41) Avail: CASI HC A03 (US Sales Only)

The space-time structure of the bimodulated ultra-relativistic electron beam (BUEB) spreading in an atmospheric plasma channel (APCh) with a combined frequency was investigated experimentally. It was shown that such a beam spreads in APCh rather steadily on the distances defined by experimental conditions. A noticeable stabilization of its cross section was observed. An agreement with the earlier proposed theoretical model modified for a bimodulated beam was noted. A conclusion about the stabilizing influence of the low-frequency BUEB current modulation on its transportation in a high-dissipative plasma channel was made. DOE

CHARACTERISTICS OF ICR-PRODUCED PERIPHERAL PLASMA IN THE URAGAN-3M TORSATRON

N. T. Besedin, V. V. Chechkin, and I. P. Fomin et al 1991 28 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(DE93-621666; KFTI-91-26) Avail: CASI HC A03 (US Sales Only)

Some plasma parameters outside the confinement volume near the last closed magnetic surface (LCMS) and in the divertor fluxes were studied by probe and microwave techniques during ICR production and heating of the plasma in the Uragan-3M torsatron. When moving around the LCMS, the steepness of the radial density, electron temperature, and potential profiles increase with distance away from the 'rib' of the LCMS. The quasi-steady radial electric field E(sub r) near the LCMS exceeds 100 V/cm and is directed outwards, opposite to the calculated ambipolar electric field inside the confinement volume. It is shown that the total flow of the diverted plasma in the spacing between two helical windings consists of a weakly mobile non-resonant component which is presumably formed at the periphery due to ionization, and a component whose value and poloidal location are sensitive to resonance conditions for RF power absorption, this flow being apparently formed by a plasma diffusing through the LCMS and/or generated near the LCMS, where the filed E(sub r) is localized. Based on plasma parameters measurements after the RF pulse is switched off, a qualitative model of peripheral plasma dynamics after the end of the RF heating is constructed. DOE

MACROSCOPIC BEHAVIOUR AND DISCRETE DYNAMO OF RFP PLASMA IN HIGH THETA DISCHARGE

H. Arimoto, K. I. Sato (Osaka Inst. of Tech., Japan.), A. Nakamura, A. Nagata (Osaka Inst. of Tech., Japan.), T. Ando, S. Kubota, S. Masamune (Kyoto Inst. of Tech., Japan.), M. Nagatsu, and T. Tsukishima Oct. 1992 20 p

(DE93-771408; PSC-26) Avail: CASI HC A03/MF A01

In this paper, the macroscopic MHD behavior of the RFP plasma produced by the high theta discharge is presented compared with that of the RFP plasma produced by the normal (ordinary) discharge, where theta is the ratio of the poloidal field at the wall to the averaged toroidal field. In the plasma generated by the high theta discharge, the mode coupling is frequently occurred due to its high magnetic shear configuration and the fluctuation is more turbulent. The discrete dynamo, which pulsively generates the toroidal flux in the high theta discharge plasma, is also examined. The results show that the discrete dynamo does not play an essential roll in the RFP dynamo. DOE

CHARACTERIZATION OF AN EXCIMER LASER-ABLATED PLASMA AND APPLICATIONS Ph.D. Thesis

Yong-Ill Lee 1992 205 p

Avail: Univ. Microfilms Order No. DA9311920

Laser ablation and the subsequent development of a high energy dense plasma are receiving increased attention for spectrochemical analysis of solid materials. Observation of the plasma using atomic emission spectroscopy is the most direct method for analysis and offers the possibility of simultaneous multielement analysis. The use of a powerful UV excimer laser for ablation is of growing interest because of the low reflectivity for most solid materials. The excimer laser improves energy coupling efficiency by offering the relatively short wavelength. The details for construction and operation of an excimer laser-ablated plasma with a wavelength of 193 nm are described. The characterization and evaluation of a new kind of excimer laser-ablated plasma and applications for direct spectrochemical analysis were investigated through time- and space-resolved spectroscopy. The characteristics of the plasma that were studied included the appearance, excitation temperature, emission spectra, ambient gas breakdown, ionization efficiency, and analytical performances. The shape, size, emission spectra, and excitation temperatures of the laser-ablated plasma are largely dependent on the atmospheric surroundings, the ambient gas composition, the pressure, and laser energy. Spatial discrimination may be desirable to increase the line-to-background (L/B) ratio in atomic emission spectroscopy. A reduced pressure (optimum pressure; 10 Torr) in argon atmosphere may be useful for laser-ablated atomic emission spectroscopy (LAAES) applications which give a high intensity and large L/B ratio for the analytical signal. Metal ion formation in the plasma varies with time as well as location in the plasma. Ion lines were emitted close to the target, while the atomic lines appeared in the further regions of the plasma. The ion concentration was dependent on the position in the plasma and reflected the local temperature in the plasma. Gas breakdown in the plasma influenced the plasma formation and the analytical emission intensity. Argon gas breakdown was observed in the plasma. The relationship between gas breakdown and the physical properties of different metal species was deduced and provided a confirmation of theoretical modeling of the laser-ablated plasma interactions. A direct spectrochemical analytical method for solid samples with good linearity was developed using the excimer laser-AES. The sensitivity of the analytical signal varied depending on the chemical matrix of the solid samples. A typical detection limit for potassium in a glass matrix was 0.13 micro-g/g and for chromium in a steel-alloy matrix was 18.7 micro-g/g. These applications demonstrate the potential of excimer laser-AES for direct spectrochemical analysis. Dissert. Abstr.

(DE93-013486; CONF-930281-7) Avail: CASI HC A03/MF A01

An improved analysis of the linear stage of the internal kink mode has been developed to include plasma rotation and finite aspect ratio effects. The linear instability growth rates are increased by the plasma rotation. A pseudo-variational, bilinear formalism is used to discretize the linear instability equations; Fourier decomposition is used in the periodic coordinate, and a mixed-finite element procedure is adopted in the radial direction. The numerical studies with the resulting PEST-like code can be used to predict the complex plasma eigenfrequencies. The finite aspect ratio results are similar to the large aspect ratio results for flow instability. The complex instability frequencies found in the 'fishbone' and TAE modes would be strong determined by the large plasma rotation velocities observed in present-day tokamak devices. These effects could be studied by using the computationally convenient bilinear form derived from the Frieman-Rotenberg equation. DOE

HELIUM TRANSPORT SCALING LAW STUDIES
Junpeng Guo and G. H. Miley Nov. 1992 9 p Presented at the Meeting of the Division of Plasma Physics of the American Physical Society, Seattle, WA, 16-20 Nov. 1992
(Contract DE-FG02-90ER-54092)
(DE93-013487; CONF-921103-11-App-B) Avail: CASI HC A02/MF A01

Impurity behavior within the tokamak fusion plasma will be a main concern for the future tokamak operation such as ITER. Thermalized alpha particles, i.e., helium 'ashes' constitute a key impurity within the plasma core. The helium ash accumulation within the tokamak plasma not only dilutes the fusion fuel, but also enhances the radiation energy loss. Eventually, these effects can prevent the fusion ignition and degrade the fusion output power even after ignition. Great progress has been made in determining the transport coefficients D(r) and V(r) with helium puffing and simulation techniques. Obviously, those results are only valid for a specific machine under certain plasma conditions. The extrapolation to other devices still remains a problem. Physically, alpha particle transport is determined by the local plasma conditions. Therefore, the D and V should be a function of the plasma parameters. In our research, we assume that the helium transport scaling law has the form of power law. By using the experiment data from helium puffing in L-mode deuterium plasma on TFRR, the scaling laws of D and V are obtained with the least square analysis. Also, the significance of helium transport scaling law to the design is discussed. DOE

ATOMIC PROCESSES RELEVANT TO POLARIZATION PLASMA SPECTROSCOPY
T. Fujimoto, F. Koike, K. Sakimoto, R. Okasaka, K. Kawasaki, K. Takiyama, T. Oda, and T. Kato Apr. 1992 155 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-753240; NIFS-Data-16) Avail: Issuing Activity (Department of Energy (DOE))

When atoms (ions) are excited anisotropically, polarized excited atoms are produced and the radiation emitted by these atoms is polarized. From the standpoint of plasma spectroscopy research, the existing data for various atomic processes that are related to the polarization phenomena are reviewed. These processes are: electron impact excitation, excitation by atomic and ionic collisions, photoexcitation, radiative recombination, and bremsstrahlung. Collisional and radiative relaxation processes of atomic polarization follow. Other topics included are: electric-field measurement, self alignment, Lyman doublet intensity ratio, and magnetic-field measurement of the solar prominence. DOE

We present an alternative approach to statistical analysis of an intermittent ideal MHD fluid in two dimensions, based on the hydrodynamical discrete vortex model applied to the Elsasser variables. The model contains negative temperature states which predict the formation of magnetic islands, but it also includes a natural limit under which the equilibrium states revert to the familiar twin-vortex states predicted by hydrodynamical turbulence theories. Numerical dynamical calculations yield equilibrium spectra in agreement with the theoretical predictions. DOE

(DE93-011892; UCRL-JC-109094; CONF-920362-46) Avail: CASI HC A03/MF A01

A streaked multiple pinhole camera technique, first used to record time- and 2-D space-resolved soft X-ray images of plasma pinches, has been implemented on laser plasmas at NOVA. The instrument is particularly useful for time-resolved imaging of small sources (less than 150 microns) such as implosions for which the necessary alignment accuracy is relaxed from less than 10 microns for a single pinhole, to 200 microns for a nine pinhole column. Results at 20 microns, 30 ps resolution are presented for greater than 2.5 keV imaging, complementing the existing 1-3 key streaked X-ray microscope capabilities at NOVA. DOE

INITIAL ASSESSMENT OF LOWER HYBRID CURRENT DRIVE IN D3-D
M. E. Fenstermacher and M. Porkolab Sep. 1992 32 p
(Contract W-7405-eng-48)
(DE93-013310; UCRL-ID-111838) Avail: CASI HC A03/MF A01

In this report we discuss the choice of rf frequency for LHCD in DIII-D, and its consequences for the operating regimes. We also discuss some Brambilla code results for particular launcher geometry, as well as edge density requirements for efficient coupling by the launcher. We present results of the ACCOME code modelling for selected frequency spectra. Finally, a summary is given, as well as suggestions for future studies. DOE

AN EMERGING UNDERSTANDING OF H-MODE DISCHARGES IN TOKAMAKS
R. J. Groebner Dec. 1992 59 p Presented at the Meeting of the Division of Plasma Physics of the American Physical Society, Seattle, WA, 16-20 Nov. 1992
(Contract DE-AC03-89ER-51114)
(DE93-012829; GA-A-21128; CONF-921103-10) Avail: CASI HC A04/MF A01

A remarkable degree of consistency of experimental results from tokamaks throughout the world has developed with regard to the phenomenology of the transition from L-mode to H-mode confinement in tokamaks. The transition is initiated in a narrow layer at the plasma periphery where density fluctuations are suppressed and steep gradients of temperature and density form in a region with large first and second radial derivatives in the upsilon(sub E) = (E x B)/B(sup 2) flow velocity. These results are qualitatively consistent with theories which predict suppression of fluctuations by shear or curvature in (upsilon)E. The required (upsilon)E flow is generated very rapidly when the magnitude of the heating power or of an externally imposed radial current exceed threshold values and several theoretical models have been developed to explain the observed changes in the (upsilon)E flow. After the transition occurs, the altered boundary conditions enable the development of improved confinement in the plasma interior on a confinement time scale. The resulting H-mode discharge has typically twice the confinement of L-mode discharges and regimes of further improved confinement have been obtained in some H-mode scenarios. DOE

STATISTICAL APPROACH TO LHCD MODELING USING THE WAVE KINETIC EQUATION
K. Kupfer, D. Moreau (Association Euratom-CEA, Saint Paul-les-Durance, France.), and X. Litaudon (Association Euratom-CEA, Saint Paul-les-Durance, France.) Apr. 1993 4 p Presented at the 10th Topical Conference on Radio Frequency Power in Plasmas, Boston, MA, 1-3 Apr. 1993
(Contract DE-AC03-89ER-51114)
(DE93-012831; GA-A-21258; CONF-9304112-5) Avail: CASI HC A01/MF A01

Recent work has shown that for parameter regimes typical of many present day current drive experiments, the orbits of the launched LH rays are chaotic (in the Hamiltonian sense), so that wave energy diffuses through the stochastic layer and fills the spectral gap. We have analyzed this problem using a statistical approach, by solving the wave kinetic equation for the coarse-grained spectral energy density. An interesting result is that the LH absorption profile is essentially independent of both the total injected power and the level of wave stochastic diffusion. DOE

INVARIANCE OF THE MOBILITY EDGE IN ANODIC TITANIUM OXIDES
N. Tit, J. W. Halley, and H. B. Shore May 1992 4 p
(DE92-642136; IC-92/85) Avail: CASI HC A01/MF A01 (US Sales Only)

A theoretical investigation to explain the electronic and optical properties of anodic rutile TiO2 thin films of different thicknesses (ranging from 5nm to 20nm) is described. There is experimental evidence that the observed gap state at 0.7eV below the edge of conduction-band is due to an oxygen vacancy. For this reason, oxygen vacancies are used as defects in our model. A comparison of the calculated bulk-photoconductivity to photospectroscopy experiment reveals that the films have bulk-like transport properties with a bandgap E(sub g) = 3.0 eV. On the other hand, a fit of the surface density of states to the scanning tunneling microscopy (STM) experiment on the (001) surfaces has suggested a surface defect density of 5% of oxygen vacancies. To resolve this discrepancy, the dc-conductivity where localization effects are included was calculated. Our results show an impurity band formation at about p(sub c) = 9% of oxygen vacancies. It was concluded that the studied films have defect densities below the threshold of impurity band formation. As a consequence the gap states seen in STM are localized (i.e. the oxygen vacancies are playing the role of trapping centers, deep levels) and the mobility edge is invariant. DOE

SYMMETRY LOWERING IN CRYSTALLINE SOLID SOLUTIONS: A STUDY OF CINNAMAMIDE-THIENYLACRYLAMIDE BY X RAY AND NEUTRON DIFFRACTION AND SOLID-STATE PHOTOCHEMISTRY
L. J. W. Shimon, Y. Weissinger-Lewin, R. K. McMullan, M. Vaida, F. Frolow, M. Lahav, and L. Leiserowitz (Weizmann Inst. of Science, Rehovoth, Israel.) 1993 48 p Presented at the Faraday Division of Royal Society of Chemistry Conference on Crystal Growth, Glasgow, England, 14-16 Spr. 1993
(Contract DE-AC02-76CH-00016)
(DE93-010871; BNL-48645; CONF-9304113-1) Avail: CASI HC A03/MF A01

Principles are outlined for symmetry lowering of a mixed crystal. A survey is given of methods used to detect reduced symmetry: changes in crystal morphology, detection of enantiomeric segregation of chiral additives in 'centrosymmetric' crystals, generation of second harmonic optical signals, optical birefringence, asymmetric photoreactions in the crystalline state and X-ray and neutron diffraction. The last two methods are applied to mixed crystals of cinnamamide host and thienylacrylamide. Diffraction demonstrated that the mixed crystals are composed of six sectors of reduced symmetry, from monoclinic centrosymmetric P2(sub 1)/c to triclinic P1 in four sectors and possibly Pc in the remaining two. The X-ray diffraction data were not sufficiently accurate for assigning the absolute structures of the PI sectors of anomalous X-ray scattering. Thus, by this method one could not ascertain the absolute orientation of the guest molecules on the surface sites through which they were selectively occluded. This ambiguity was resolved by assignment of the absolute configuration of the chiral heterophotodimers, between host and guest, in enantiomeric excess in the PI sectors, after irradiation with UV light. This leads to the conclusion that the selective occlusion of thienylacrylamide arises from replacement of attractive C-H...pi(electron) interactions between host molecules by a repulsive sulfur (lone pair electron)...pi(electron) interactions between guest and host at the crystal surfaces. EFFECT OF A DISTRIBUTION OF EXCHANGE PARAMETERS WITHIN A SIMPLE LOCALIZED-ITINERANT MODEL
L. Iannarella, A. P. Guimaraes, and X. A. daSilva 1991 16 p
(DE93-610314; CBPF-NF-034/91) Avail: CASI HC A03/MF A01 (US Sales Only)

The magnetic behavior at $T = 0$ K of a system consisting of conduction electrons coupled to localized electrons submitted to an axial crystal field is studied in the molecular field approximation. We assume that the exchange parameter J varies spatially with a Gaussian probability distribution. We define an average ionic magnetic moment and obtain the condition for spontaneous magnetic order, involving the crystal field parameter, the width and the mean value of the exchange parameter distribution. We also obtain graphs of the magnetic moment versus mean value of the exchange parameter distribution, for different distributions showing that the distribution of J's reduces the rate of increase of magnetization versus the mean J. ENHANCED STABILITY OF MAGIC CLUSTERS: A CASE STUDY OF ICOSAHEDRIC Al(SUB 12)X, X=B, Al, Ga, C, Si, Ge, Ti, As
X. G. Gong and V. Kumar Oct. 1992 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-613644; IC-92/314) Avail: CASI HC A03 (US Sales Only)

We present results of the electronic structure and stability of some 40 valence electron icosahedric Al12(X) (where X=B, Al, Ga, C, Si, Ge, Ti, and As) clusters within the local spin density functional theory. It is shown that the stability of the Al13 cluster can be substantially enhanced by proper doping. For neutral clusters, substitution of C at the center of the icosahedron leads to the largest gain in energy. However, Al12B(-) is the most bounded in this family. These results are in agreement with the recent experiments which also find Al12B(-) to be highly abundant. DOE

A LATTICE GAS MODEL FOR ENZYME KINETICS WITH ALTERNATE INTERACTIONS
R. Mejdani Sep. 1992 19 p
(DE93-613027; IC-92/281) Avail: CASI HC A03/MF A01 (US Sales Only)

We have shown that by using three equivalent different techniques (the transfer matrix method, the correlated walks' theory, and the partition point technique) for a lattice gas model in one dimension with alternate nearest neighbor ferromagnetic interactions, we can find a new equation of the enzyme kinetics. This equation in the limit of no interaction between sites reduces to the classical Michaelis-Henri equation, while for the same interaction between sites reduces to another equation, which we have obtained before. This new equation can be useful for the experimental investigation. DOE

ORBITAL GLASS IN HTSC
F. V. Kusmartsev Oct. 1992 11 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-613988; IC-92/309) Avail: CASI HC A03 (US Sales Only)

The physical reasons why the orbital glass may exist in granular high-temperature superconductors and the existing experimental data that appeared recently are discussed. The orbital glass is characterized by the coexistence of the orbital paramagnetic state with the superconducting state and occurs at small magnetic fields H less than H(sub c0) much less than H(sub c1). The transition in orbital glass arises at the critical field H(sub c0) which is inversely proportional to the surface cross-area S of an average grain. In connection with theoretical predictions the possible experiments are proposed. DOE

Proceedings held in Boston, MA, 30 Nov. - 4 Dec. 1992
(Contracts N00014-93-1-0215; DAAL03-92-G-0418)
(AD-A265675) Avail: CASI HC A21/MF A04

This proceedings volume includes most of the invited and contributed papers presented as Symposium U, Solid State Ionics, at the 1992 MRS Fall meeting in Boston, Massachusetts, U.S.A. The Symposium covered material aspects of solid state ionics, theory of ion transfer in solids, ionically and electronically conductive polymers and their application in solid state devices, and various in-situ and ex-situ techniques for materials characterization. The first part of this proceedings volume deals with physics and chemistry of insertion compounds and application of these in advanced solid state batteries. The optical and electrochemical properties of insertion compounds are also presented. The second part of the proceedings deals with ionic and electronic conductive polymers. A new class of rubbery phase polymer electrolytes and their structure-conductivity relationship are presented. Physical and chemical properties of polymer electrolytes and electrodes and their application in solid state devices are presented. DTIC

KINETICS OF HIGH CONCENTRATION ARSENIC DEACTIVATION AT MODERATE TO LOW TEMPERATURES
S. Luning (Stanford Univ., CA.), P. M. Rousseau (Stanford Univ., CA.), P. B. Griffin (Stanford Univ., CA.), J. D. Plummer (Stanford Univ., CA.), and P. G. Carey 14 Oct. 1992 5 p Presented at the International Electron Devices Meeting, San Francisco, CA, 6-9 Dec. 1992
(Contract W-7405-eng-48)
(DE93-013349; UCRL-JC-111945; CONF-921204-2) Avail: CASI HC A01/MF A01

This work investigates the kinetics of arsenic deactivation at temperatures from 500 to 800 C and for concentrations between 1 x 10(exp 20) and 1 x 10(exp 21)/cu cm. Using profiles created by repeated laser melt annealing, the authors determined mobility as a function of both active and inactive dopant concentration and then characterized the dynamics of carrier deactivation. Retrograde resistivity versus concentration was observed at high doses, which is explained by a mobility reduction due to the inactive arsenic and by retrograde electrical activity of the dopant itself. BOND DISTORTION AND ELECTRON TRAPPING IN CHARGED C60
X. Sun, R. T. Fu (Fudan Univ., Shanghai, China.), R. L. Fu (Academia Sinica, Shanghai, China.), and H. J. Ye (Academia Sinica, Shanghai, China.) Oct. 1992 19 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-613642; IC-92/310) Avail: CASI HC A03 (US Sales Only)

By considering both electron-electron and electron-lattice interactions, the effect of charge transfer on the bond structure and electronic states of doped C60 is studied without configuration limitation. The results show that the electron interaction does not eliminate the layer structure of the bond distortion and the self-trapping of transferred electrons. There still exist two localized electronic states, which possess laminar wave functions, and four nonequivalent groups of carbon atoms, which induce a fine-structure in the NMR spectrum line. DOE

SPONTANEOUS SYMMETRY BREAKING IN QCD
Hirofumi Yamada Mar. 1992 25 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-753080; INS-918) Avail: CASI HC A03

We study dynamical chiral symmetry breaking in QCD by the use of the generalized Hartree-Fock method. The low energy quark mass is calculated to the second order of diagrammatic expansion around shifted perturbative vacuum where quarks are massive. We show that the low energy mass is finite and renormalization group invariant. We find that the finite mass gap emerges as the solutions of gap equation and stationarity condition, thereby breaking the chiral symmetry. We also discuss the possibility that the breaking solution may exist up to all orders. DOE

SURFACE-ENHANCED RAMAN SPECTROSCOPY OF ELECTROACTIVE FILMS OF C60 AND AN Ir-C60 COMPLEX ON GOLD: SYMMETRY LOWERING, ELECTRON LOCALIZATION, AND COUNTERACTION EFFECTS Technical Report
Yun Zhang, Yuhua Du, John R. Shapley, and Michael J. Weaver Apr. 1993 19 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1409)
(AD-A265934; TR-136) Avail: CASI HC A03

Surface-enhanced Raman (SER) spectra are reported for thin films of C60 and (eta5-C9H7)Ir(CO)(eta2-C60) on gold electrodes in acetonitrile. The latter spectra display the hallmarks of vibrational symmetry lowering for C60 arising from metal coordination, involving splitting of the normally degenerate H(sub g) modes and the appearance of vibrationally forbidden bands. Only a milder selection rule relaxation is observed for SERS of uncoordinated C60. Electroreduction of both C60 and the Ir-C60 complex yielded similar frequency downshifts in the Ag pentagonal pinch mode. This indicates that electron addition to the latter is fullerene localized. These spectral shifts are sensitive to the nature of the countercation. DTIC

CRACK SUPPRESSION IN GaInSb BUFFER LAYERS INITIALLY UNDER TENSILE STRESS
T. J. Drummond and S. R. Lee 1992 22 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 12-16 Apr. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC04-76DP-00789)
(DE93-012839; SAND-92-2498C; CONF-930405-2) Avail: CASI HC A03

Epitaxial III-V compound semiconductor buffer layers typically relieve tensile stress by mixed crack and misfit dislocation formation. Crack suppression by p-doping GaInSb step graded buffers grown on InSb substrates by MBE is demonstrated. This complements a similar demonstration for InAsSb buffers grown by MOCVD. The depth dependence and reproducibility of the stress relaxation have been quantified using a novel k-map x-ray analysis. A model in which the p-doping enhances the nucleation and subsequent climb of dislocations has been formulated to explain the result. This model should also apply to other III-V buffer systems such as GaAsP/GaAs and InGaAs/InP. DOE

CONFINEMENT OF ACOUSTICAL MODES DUE TO THE ELECTRON-PHONON INTERACTION WITHIN 2D-ELECTRON GAS
V. A. Kochelap and O. Gulseren (Bilkent Univ., Ankara, Turkey.) Sep. 1992 18 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-613910; IC-92/282) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

The confinement of acoustical modes within 2DEG due only to the electron-phonon interaction is studied. The confined modes split out from the bulk phonons even at uniform lattice parameters, when the 2DEG is created by means of modulation doping. The effect is more pronounced when the wave vector q of the modes increases and is maximum at q = 2k(sub F) (k(sub F) is the Fermi wave vector). In the case of several electron sheets the additional features of the confinement effect appear. In the limit of the strong electron-phonon coupling and high surface concentration of the electrons the considered system can suffer Peierls-type phase transition. In this case periodical deformation of the lattice and charge density wave are confined within the electron sheet. DOE

RAPID THERMAL PROCESSING FOR STRAINED-LAYER SEMICONDUCTOR DEVICES
J. C. Zolper and D. R. Myers 1993 10 p Presented at the Spring

Meeting of the Materials Research Society, San Francisco, CA, 12-16 Apr. 1993
(Contract DE-AC04-76DP-00789)
(DE93-013754; SAND-93-1020C; CONF-930405-6) Avail: CASI HC A02/MF A01

Strained-layer semiconductors have revolutionized modern heterostructure devices by exploiting the modification of semiconductor band structure associated with the coherent strain of lattice-mismatched heteroepitaxy. The modified band structure improves transport of holes in heterostructures and enhances the operation of semiconductor lasers. Strained-layer epitaxy also can create materials whose band gaps match wavelengths (e.g. 1.06 and 1.32 microns) not attainable in ternary epitaxial systems lattice matched to binary substrates. Other benefits arise from metallurgical effects of modulated strain fields on dislocations. Lattice mismatched epitaxial layers that exceed the limits of equilibrium thermodynamics will degrade under sufficient thermal processing by converting the as-grown coherent epitaxy into a network of strain-relieving dislocations. After presenting the effects of strain on band structure, the authors describe the stability criterion for rapid-thermal processing of strained-layer structures and the effects of exceeding the thermodynamic limits. Finally, device results are reviewed for structures that benefit from high temperature processing of strained-layer superlattices. DOE

ELECTRONIC CHARACTERIZATION OF DEFECTS IN NARROW GAP SEMICONDUCTORS Semiannual Report, 25 Nov. 1992 - 25 Jun. 1993
James D. Patterson 25 Jun. 1993 59 p
(Grant NAG8-941)
(NASA-CR-193568; NAS 1.26:193568) Avail: CASI HC A04/MF A01

The study of point defects in semiconductors has a long and honorable history. In particular, the detailed understanding of shallow defects in common semiconductors traces back to the classic work of Kohn and Luttinger. However, the study of defects in narrow gap semiconductors represents a much less clear story. Here, both shallow defects (caused by long range potentials) and deep defects (from short range potentials) are far from being completely understood. In this study, all results are calculational and our focus is on the chemical trend of deep levels in narrow gap semiconductors. We study substitutional (including antisite), interstitial and ideal vacancy defects. For substitutional and interstitial impurities, the efects of relaxation are included. For materials like Hg(1-x)Cd(x)Te, we study how the deep levels vary with x, of particular interest is what substitutional and interstitial atoms yield energy levels in the gap i.e. actually produce deep ionized levels. Also, since the main technique utilized is Green's functions, we include some summary of that method. Derived from text

SZILARD-CHALMERS EFFECT IN SOLID HIO4.2H2O BY NEUTRON IRRADIATION
Salaheddin Takriti Sep. 1992 19 p In ARABIC Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-617173; AECS-C/FRSR-59) Avail: CASI HC A03 (US Sales Only)

The Szilard-Chalmers effect in solid was investigated. In order to study the initial distribution of (128)IO4 as a function of neutron flux, samples were irradiated utilizing both the manual vertical irradiation channel and the thermal column of the ET-RR-1 Research Reactor in Egypt. The initial retention was reached a maximum of 40% after 120 minutes at 5.5 x 10(sup 8) ns(exp -1)cm(exp -2). The data was analyzed using a first order reaction. As a result, the activation energy and the vibration constant were found to be E = 0.95 eV and K = 2.82 x 10(sup 11), respectively. Kinetics comparison of the dehydration and irradiation reactions for this solid shows disorder in the crystallographic form. Such disorder may be the result of dehydration or irradiation reaction, where the loss of water molecule will lead to formation of vacancies which, in turn, are responsible for the distribution process. DOE

RADIATION DEFECT PRODUCTION IN InAs CRYSTALS UNDER ELECTRON IRRADIATION [RADIATSIONNOE DEFEKTOOBRAZOVANIE V KRISTALLAKH INAS PRI EHLEKTRONNOM OBLUCHENII]
E. Y. Brajlovskij, D. B. Goer, Y. I. Gutich, and I. G. Megela 1991 27 p In RUSSIAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-617202; KIYal-91-29) Avail: CASI HC A03 (US Sales Only)

The defect-production and annealing processes in InAs under 2.0/14.5 MeV electron irradiation up to a dose 7 x 10(exp 18) electrons/cm(exp 2) at 77 and 293 K have been investigated. It was shown that in undoped n-InAs crystals the n-value increase with irradiation dose at 293 K leads to the dependence (delta)n approximately = phi(exp 0.5) at all fluences. On the contrary, in the case of irradiation of n-InAs crystals doped with Sn and Te (n greater than 5 x 10(exp 17)) it was found that the n-value begins to increase after 'exhaustion' of the doping atoms only as a result of the RD-doping atom interaction. From optical free-carrier absorption measurements a decrease power index r in the dependence alpha approximately = omega(sup -r) is observed as a result of irradiation that was explained by the influence of local deformation fields in the vicinity of the RD on the scattering mechanisms. GAUGE INDEPENDENCE OF THE A(SUB 0)-CONDENSATE
V. V. Skalozub 1992 13 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-617681; ITP-92-12) Avail: CASI HC A03 (US Sales Only)

The problem of gauge dependence of the zero gauge field component condensate. A(sub 0)=const, in the framework of finite temperature SU(2) gluodynamics is investigated. In straight-forward calculations it is shown that the two-loop effective action W(A(sub 0),(zeta)) satisfies the generalized Nielsen identity. Thus, the gauge invariance of the A(sub 0)-condensation is proved. DOE

SYNTHESIS AND PROPERTIES OF NANOPHASE MATERIALS

R. W. Siegel Mar. 1993 25 p Presented at the 3rd Joint Conference of European East-West Conference on Materials and Processes and European Materials Research Society Fall Meeting, Strasbourg, France, 3-6 Nov. 1992
(Contract W-31-109-eng-38)
(DE93-011757; ANL/MSD/CP-76872; CONF-921121-2) Avail: CASI HC A03/MF A01

Nanophase materials, with their grain sizes or phase dimensions in the nanometer size regime, are now being produced by a wide variety of synthesis and processing methods. The interest in these new ultrafine-grained materials results primarily from the special nature of their various physical, chemical, and mechanical properties and the possibilities to control these properties during the synthesis and subsequent processing procedures. Since it is now becoming increasingly apparent that their properties can be engineered effectively during synthesis and processing and that they can also be produced in quantity, nanophase materials should have considerable potential for technological development in a variety of applications. Some of the recent research on nanophase materials related to their synthesis and properties is briefly reviewed and the future potential of these new materials is considered. DOE

MICROSTRUCTURE AND ASSOCIATED PROPERTIES OF YB2Cu3O(x) SUPERCONDUCTORS PREPARED BY MELT PROCESSING TECHNIQUES
U. Balachandran, W. Zhong, C. A. Youngdahl, and R. B. Poeppel Mar. 1993 19 p Presented at the Annual Meeting of The Metallurgical Society, Denver, CO, 21-25 Feb.1993
(Contract W-31-109-eng-38)
(DE93-010675; ANL/MCT/CP-76965; CONF-930202-6) Avail: CASI HC A03/MF A01

From the standpoint of applications, melt-processed bulk YBa2Cu3O(x) (YBCO) superconductors are of considerable interest. We have studied the microstructure and levitation force of melt-processed YBCO, YBCO plus Y2BaCuO5, and YBCO plus Pt samples. Large single crystalline samples, grown using a seeding technique, were also studied. The levitation force is highest in melt-processed samples made by the seeding technique. DOE

GRAIN BOUNDARIES IN COMPLEX OXIDES
Yet-Ming Chiang May 1993 4 p
(Contract DE-FG02-87ER-45307)
(DE93-013986; DOE/ER-45307/5) Avail: CASI HC A01/MF A01

A quantitative comparison was achieved between space charge theory and segregation at grain boundaries in the model system TiO2. The ionic space charge can be titrated from negative to positive potential. A space charge model was developed that includes the lattice defect chemistry. Defect formation energies in the Frenkel pair for TiO2 were studied. Grain boundary enthalpy was measured during coarsening. It was shown that it is the barium vacancy that forms near surfaces in donor-doped BaTiO3 electroceramics during oxidative-cooling. DOE

PROCESSING AND TRANSPORT PROPERTIES OF HIGH J(SUB c) SILVER CLAD BI-2223 TAPES AND COILS
P. Haldar (Intermagnetics General Corp., Guilderland, NY.), J. G. Hoehn, Jr. (Intermagnetics General Corp., Guilderland, NY.), U. Balachandran, and L. R. Motowidlo (IGC/Advanced Supercomputers, Inc., Waterbury, CT.) Feb. 1993 12 p Presented at the Annual Meeting of The Metallurgical Society, Denver, CO, 21-25 Feb. 1993
(Contract W-31-109-eng-38)
(DE93-010674; ANL/MCT/CP-79135; CONF-930202-7) Avail: CASI HC A03/MF A01

The powder-in-tube process has been used to fabricate long lengths of flexible, high J(sub c), silver clad Bi-2223 HTS conductors. By improving thermo-mechanical processing and precursor powder preparation we have succeeded in achieving J(sub c)'s exceeding 4 x 10(exp 4) A/sq cm at liquid nitrogen (77K) and greater than 10(exp 5) A/sq cm at liquid helium (4.2K) and liquid neon (27K) temperatures for short tape samples. Detailed measurements with high applied magnetic fields are reported. Several long tapes up to 10 meters in length have also been fabricated and co-wound into small superconducting pancake coils using the 'wind-and-react' approach. Transport measurements at 77K and 4.2K for these coils are also reported. DOE

INTERATOMIC INTERACTIONS IN BCC AND FCC LATTICES OF TRANSITION METALS [MEZHATOMNYE VZAIMODEJSTVIYA V OTSK-GTSK PEREKHODNYKH METALLAKH]
V. V. Gann and V. I. Pokhodyashchij 1991 22 p In RUSSIAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-621541; KFTI-91-13) Avail: CASI HC A03 (US Sales Only)

A 3-parameter model for determining the coupling energy in transition metals with cubic lattices is proposed. The parameters of this model were adjusted to account for experimental data concerning the shear module, vacancy formation energy, and sublimation energy values. Elastic and dynamic properties of crystal lattices of some transition metals were calculated. It is concluded that the proposed model describes the properties of transition metals in a single manner and with a good degree of accuracy. DOE

HIGH TEMPERATURE STABILITY, INTERFACE BONDING, AND MECHANICAL BEHAVIOR IN (BETA)-NIAI AND NI3AI MATRIX COMPOSITES WITH REINFORCEMENTS MODIFIED BY ION BEAM ENHANCED DEPOSITION
D. S. Grummon 21 Jan. 1993 7 p
(Contract DE-FG02-85ER-45205)
(DE93-013977; DOE/ER-45205/8) Avail: CASI HC A02/MF A01

Diffusion-bonded NiAl-Al2O3 and Ni3Al-Al2O3 couples were thermally fatigued at 900 C for 1500 and 3500 cycles. The fiber-matrix interface weakened after 3500 cycles for the Saphikon fibers, while the Altex, PRD-166, and FP fibers showed little, if any, degradation. Diffusion bonding of fibers to Nb matrix is being studied. Coating the fibers slightly increases the tensile strength and has a rule-of-mixtures effect on elastic modulus. Push-out tests on Sumitomo and FP fibers in Ni aluminide matrices were repeated. Al2O3 was evaporated directly from pure oxide rod onto acoustically levitated Si carbide particles, using a down-firing, rod-fed electron beam hearth; superior coatings were subsequently produced using concurrent irradiation with 200-eV argon ion-assist beam. The assist beam produced adherent films with reduced tensile stresses. In diffusion bonding in B-doped Ni3Al matrices subjected to compressive bonding at 40 MPa at 1100 C for 1 hr, the diffusion barriers failed to prevent catastrophic particle-matrix reaction, probably because of inadequate film quality. AlN coatings are currently being experimented with, produced by both reactive evaporation and by N(+)-ion enhanced deposition. A 3-kW rod-fed electron-beam-heated evaporation source has been brought into operation. DOE

TIME-RESOLVED OPTICAL STUDIES OF CHARGE RELAXATION AND CHARGE TRANSFER AT ELECTRODE INTERFACES
1992 11 p
(Contract DE-FG02-89ER-14062)
(DE93-013985; DOE/ER-14062/3) Avail: CASI HC A03/MF A01

The following key components were identified in a quantitative model of carrier relaxation in semiconductor electrodes: nonlinear aspects of nonradiative and radiative recombination, effect of space charge field on carrier dynamics, self-absorption effects in direct gas semiconductors, and influence of surface state population kinetics on charge carrier recombination. For CdSe, the first three are operative (no direct proof of the last one). A realistic kinetic model for carrier recombination in the bulk of CdSe was used which includes important nonlinear effects, both radiative and nonradiative. The change in interfacial recombination velocity with the chemical nature of the interface was studied (n-CdSe/silane interfaces). Temperature effect (278 to 328 K) on fluorescence decay of n-CdSe in contact with 0.5 M KOH was found to be weak. An analytical solution was obtained for time-resolved fluorescence from electrodes under potential bias, and is being tested. Fluorescence work on a different material, CdS, indicate different recombination kinetics; this material was used to directly pump an optical transition of a surface state. DOE

FEMTOSECOND DYNAMICS, PHOTOEXCITATION, AND ESR SPECTRA OF MX CHAIN SOLIDS Professional Paper
J. T. Gammel, A. Saxena, L. Batistic, and A. R. Bishop Mar. 1993 10 p
(AD-A264689) Avail: CASI HC A02/MF A01

Nonlinear adiabatic dynamics and ESR spectra associated with nonlinear excitations in MX chain (M = Pt and X = CL,BrI) materials are numerically studied within a discrete, 3/4-filled, two-band, tight-binding extended Peierls-Hubbard model. Both Hartree-Fock (HF) adiabatic molecular relaxation and molecular dynamics techniques are employed to investigate the time evolution of solitons, polarons, bipolarons in charge-density-wave (CDW) ground state materials. The time evolution of excitons, defect pairs and/or breathers is studied subsequent to photoexcitation. The ESR spectra associated with the resulting spin carrying nonlinear excitations such as neutral solitons, triplet excitons as well as electron and hole polarons are then calculated within the above model. The superhyperfine structure in the ESR spectra is attributed to a small spin density present on the halogen sublattice. DTIC

DYNAMIC STUDIES OF CRYSTAL GROWTH USING THE AFM
A. J. Gratz, P. E. Hillner (California Univ., Santa Barbara.), S. Manne (California Univ., Santa Barbara.), and P. K. Hansma (California Univ., Santa Barbara.) 15 Apr. 1992 4 p Presented at the Society of Photo-Optical Instrumentation Engineers (SPIE) International Symposium on Laser Spectroscopy, Los Angeles, CA, 19-24 Jan. 1992
(Contract W-7405-eng-48)
(DE93-009549; UCRL-JC-110510; CONF-920124-29) Avail: CASI HC A01/MF A01

Recent advances in atomic force microscopy (AFM) technology allow direct observation of solution growth and dissolution (etching) processes, processes that are important in industry and nature, and direct tests of crystal growth models. We present results of studies of calcite and quartz including real-time, in situ observations. While both crystals experience layer growth/dissolution, calcite grows by direct addition of material to growth steps without an important contribution from surface diffusion; quartz surfaces are consistent with more traditional, BCF-type growth models. Dynamic AFM observations of growth processes may allow optimization of industrial systems. DOE

TEXTURE ANALYSIS OF HIGH Tc SUPERCONDUCTORS Ph.D. Thesis
Anthony Charles Biondo 1992 172 p
Avail. Univ. Microfilms Order No. DA9311928

The effect of processing on the quantitative texture developed for the high T(sub c) superconductors Y1Ba2Cu3O(7-delta) and Bi2Sr2Ca1Cu2O8 was studied. Due to the anisotropic nature of the properties of these compounds, it is anticipated that this preferred orientation will effect the bulk properties of the processed samples. An effort to predict the properties using the quantitative texture data available in orientation distribution functions was made. Three methods of processing were studied: conventional processing of Y1Ba2Cu3O(7-delta), melt texture processing of Y1Ba2Cu3O(7-delta), and powder-in-tube processing of Bi2Sr2Ca1Cu2O8. The first two processing methods resulted in critical current densities which did not change with different preferred orientations. Thus, property prediction using the texture data was not possible. The third method did result in an increase of critical current density as the strength of the texture increased. Two models were used to predict the critical current density of these samples using the quantitative texture data. The first model used the J(sub c) anisotropy between the plane and the c-axis for the Bi2Sr2Ca1Cu2O8 compound as input; the anisotropy which best fit the data was 20:1. The second model checked the grain to grain misorientation using three different criteria for a strong link. The critical misorientation angle for a strong link was found to be 10 degrees. Dissert. Abstr.

MEMORY EFFECTS IN THE ORGANOMETALLIC CHEMICAL BEAM EPITAXY OF COMPOUND SEMICONDUCTORS Final Report, 12 Jan. 1989 - 31 May 1993
Klaus J. Bachmann 1993 57 p
(Grant NAG1-1100)
(NASA-CR-193106; NAS 1.26:193106) Copyright Avail: Issuing Activity

The final report on memory effects in the organometallic chemical beam epitaxy of compound semiconductors is presented. The goal is the improvement of the control of the composition of heterostructures under the conditions of chemical beam epitaxy (CBE) and related low pressure chemical vapor deposition methods. The linkage to NASA's mission is the opportunity for containerless processing in space which is expected to significantly reduce memory effects in the fabrication of compound semiconductor heterostructures and heterostructures that integrate compound semiconductors with silicon technology. For individual titles, see N94-11440 through N94-11443.

REMOTE PLASMA ENHANCED CHEMICAL VAPOR DEPOSITION OF GaP WITH IN SITU GENERATION OF PHOSPHINE PRECURSORS
S. W. Choi, G. Lucovsky, and Klaus J. Bachmann *In its* Memory Effects in the Organometallic Chemical Beam Epitaxy of Compound Semiconductors 1993 4 p Repr. from J. Vac. Sci. Technol. B (American Vacuum Society), v. 10, no. 3, May/Jun. 1992 p 1070-1073 (For primary document see N94-11439 01-76)
Avail: Issuing Activity

Thin homoepitaxial films of gallium phosphide (GaP) were grown by remote plasma enhanced chemical vapor deposition utilizing in situ generated phosphine precursors. The GaP forming reaction is kinetically controlled with an activation energy of 0.65 eV. The increase of the growth rate with increasing radio frequency (rf) power between 20 and 100 W is due to the combined effects of increasingly complete excitation and the spatial extension of the glow discharge toward the substrate, however, the saturation of the growth rate at even higher rf power indicates the saturation of the generation rate of phosphine precursors at this condition. Slight interdiffusion of P into Si and Si into GaP is indicated from GaP/Si heterostructures grown under similar conditions as the GaP homojunctions.

LATTICE-MATCHED HETEROEPITAXY OF WIDE GAP TERNARY COMPOUND SEMICONDUCTORS

Klaus J. Bachmann *In its* Memory Effects in the Organometallic Chemical Beam Epitaxy of Compound Semiconductors 1993 11 p Repr. from Materials Research Society Symposium Procedures, v. 242, 1992 p 707-717 (For primary document see N94-11439 01-76)
Avail: Issuing Activity

A variety of applications are identified for heteroepitaxial structures of wide gap I-III-VI(sub 2) and II-IV-V(sub 2) semiconductors, and are assessed in comparison with ternary III-V alloys and other wide gap materials. Non-linear optical applications of the I-III-VI(sub 2) and II-IV-V(sub 2) compound heterostructures are discussed, which require the growth of thick epitaxial layers imposing stringent requirements on the conditions of heteroepitaxy. In particular, recent results concerning the MOCVD growth of ZnSi(x)Ge(1-x)P2 alloys lattice matching Si or GaP substrates are reviewed. Also, heterostructures of Cu(z)Ag(1-z)GaS2 alloys that lattice-match Si, Ge, GaP, or GaAs substrates are considered in the context of optoelectronic devices operating in the blue wavelength regime. Since under the conditions of MOCVD, metastable alloys of the II-IV-V(sub 2) compounds and group IV elements are realized, II-IV-V(sub 2) alloys may also serve as interlayers in the integration of silicon and germanium with exactly lattice-matched tetrahedrally coordinated compound semiconductors, e.g. ZnSi(x)Ge(1-x)P2. ORGANOMETALLIC CHEMICAL VAPOR DEPOSITION AND CHARACTERIZATION OF ZnGeP2/GaP MULTIPLE HETEROSTRUCTURES ON GaP SUBSTRATES

G. C. Xing and Klaus J. Bachmann *In its* Memory Effects in the Organometallic Chemical Beam Epitaxy of Compound Semiconductors 1993 13 p (For primary document see N94-11439 01-76)
(Grant NSF DMR-92-02210)
Avail: Issuing Activity

The growth of ZnGeP2/GaP double and multiple heterostructures on GaP substrates by organometallic chemical vapor deposition is reported. These epitaxial films were deposited at a temperature of 580 C using dimethylzinc, trimethylgallium, germane, and phosphine as source gases. With appropriate deposition conditions, mirror smooth epitaxial GaP/ZnGeP2 multiple heterostructures were obtained on (001) GaP substrates. Transmission electron microscopy (TEM) and secondary ion mass spectroscopy (SIMS) studies of the films showed that the interfaces are sharp and smooth. Etching study of the films showed dislocation density on the order of 5x10(exp 4)cm(sup -2). The growth rates of the GaP layers depend linearly on the flow rates of trimethylgallium. While the GaP layers crystallize in zinc-blende structure, the ZnGeP2 layers crystallize in the chalcopyrite structure as determined by (010) electron diffraction pattern. This is the first time that multiple heterostructures combining these two crystal structures were made. Author (revised)

ORGANOMETALLIC CHEMICAL VAPOR DEPOSITION AND CHARACTERIZATION OF ZnGe(1-x)Si(x)P2-Ge ALLOYS ON GaP SUBSTRATES

G. C. Xing, Klaus J. Bachmann, J. B. Posthill (Research Triangle Inst., Research Triangle Park, NC.), and M. L. Timmons (Research Triangle Inst., Research Triangle Park, NC.) *In its* Memory Effects in the Organometallic Chemical Beam Epitaxy of Compound Semiconductors 1993 7 p Repr. from Journal of Crystal Growth 113 (Netherlands, Elsevier Science Publishers B.V.), 1991 p 113-119 (For primary document see N94-11439 01-76)
Avail: Issuing Activity

The epitaxial growth of ZnGe(1-x)Si(x)P2-Ge alloys on GaP substrates by open tube organometallic chemical vapor deposition (OMCVD) is reported. The chemical composition of the alloys characterized by energy dispersive X-ray spectroscopy shows that alloys with x up to 0.13 can be deposited on (001) GaP. Epitaxial growth with mirror smooth surface morphology was achieved for x less than or equal to 0.05. Transmission electron microscopy (TEM) micrographs of these alloys show specular epitaxy and the absence of microstructural defects indicating a defect density of less than 10(exp 7) cm(sup -2). Selected area electron diffraction pattern of the alloy shows that the epitaxial layer crystallizes in the chalcopyrite structure with relatively weak superlattice reflections indicating certain degree of randomness in the cation sublattice. Hall measurements show that the alloys are p-type, like the unalloyed films; the carrier concentration, however, dropped about 10 times from 2 x 10(exp 18) to 2 x 10(exp 17) cm(sup -3). Absorption measurements indicate that the band tailing in the absorption spectra of the alloy was shifted about 0.04 eV towards shorter wavelength as compared to the unalloyed material. Diodes fabricated from the n(+)-GaP/p-ZnSiP2-ZnGeP2-Ge heterostructure at x = 0.05 have a reverse break-down voltage of -10.8 V and a reverse saturation current density of approximately 6 x 10(exp -8) A/sq cm. APICAL Cu-O BOND IN YBa2Cu3O(7-DELTA) SUPERCONDUCTORS BY XAFS

E. A. Stern (Washington Univ., Seattle.), M. Qian (Washington Univ., Seattle.), Y. Yacoby (Hebrew Univ., Jerusalem, Israel.), S. M. Heald, and H. Maeda (Okayama Univ., Japan.) 1993 5 p Presented at the 2nd Israeli International Conference on High Tc Superconductivity, Elat, Israel, 4-7 Jan. 1993
(Contracts DE-AC02-76CH-00016; DE-FG06-90ER-45425)
(DE93-010861; BNL-48568; CONF-930107-1) Avail: CASI HC A01/MF A01

Careful Cu K-edge X-ray absorption fine structure (XAFS) measurements on oriented powders of YBa2Cu3O(7 - delta) were made as a function of temperature, of delta, T(sub c), method of preparation, and grain size. The XAFS data were analyzed for the Cu(1) - O(4) apical bond distance distribution. All samples indicated evidence for a double-peak in the distribution with a splitting of 0.1 A, with the clearest case for the delta approximately equal to 0 samples occurring for the T(sub c) = 89K 20 microns grain samples and the least clear one for the 5 micron grain T(sub c) = 93K sample. There is no significant temperature dependence of the splitting. Because the XAFS evidence for the splitting depends on a small signal, it is prudent to verify its existence by other independent measurements. DOE

AN INDIUM GALLIUM ARSENIDE CHARGE-COUPLED DEVICE (CCD) FOR 1-3 MICRON IMAGING Final Report, 1 Jul. 1992 - 15 Apr. 1993
Gregory H. Olsen and Marshall J. Cohen 28 May 1993 23 p
(Contract DAAL03-92-C-0039)
(AD-A266134; ARO-30480.1-EL-SBI) Avail: CASI HC A03/MF A01

The present program was the most ambitious and had as its primary objective the fabrication of an InGaAs resistive gate CCD with a long term goal of developing 1-3 micrometer InGaAs two dimensional imaging CCD's. The 1-3 micrometer band, at present, is ill-served for imaging. The existence of room temperature imager sensitive to this wavelength range is important for a wide variety of defense, scientific, and commercial applications. Operability at room temperature will allow the camera to be miniaturized, reduce its cost, and increase its ruggedness making it well suited for field applications. As a moderate-sensitivity thermal imager, cameras in this range will be able to detect on-coming vehicles and missiles as well as monitor manufacturing processes. The wavelength band also provides a better match to the natural illumination spectrum of the night sky providing enhance Night Vision capability. When combined with long wavelength (ca. 1.55 micrometer) illumination covert eye-safe surveillance is possible. Finally, one and two dimensional InGaAs arrays will span the gap between silicon based focal plane arrays and CCD's and middle infrared imagers and Fourier spectrometers for near infrared spectroscopic applications. LOW ENERGY ELECTRON DIFFRACTION AND CYCLIC VOLTAMMETRY STUDIES OF FLAME-ANNEALED PLATINUM SINGLE CRYSTALS
F. H. Feddrix, E. B. Yeager, and B. D. Cahan 23 Apr. 1993 9 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-90-J-1212)
(AD-A263566; TR-90-ONR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Low energy electron diffraction (LEED) and cyclic voltammetry were used to examine the surface structure of flame-annealed platinum (100), (110), and (111) electrodes. Well-defined LEED patterns were obtained for these surfaces but only after heat treatment in vacuo at 400 C in order to remove surface contaminants. The cyclic voltammograms correspond to those expected for these low index platinum surface from prior studies. DTIC

GaAs PCSS: HIGH GAIN SWITCHING AND DEVICE RELIABILITY
F. J. Zutavern, G. M. Loubriel, D. L. McLaughlin, M. W. OMalley, W. D. Helgeson, and G. J. Denison 1992 5 p Presented at the OE/LASE 1993: International Society for Optical Engineering (SPIE) Conference, Los Angeles, CA, 16-23 Jan. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC04-76DP-00789)
(DE93-009851; SAND-92-1636C; CONF-930159-23) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

Characteristics of GaAs photoconductive semiconductor switches (PCSS) during the initiation and sustaining phases of high gain switching are studied in this paper. Infrared electro-photoluminescence data are presented which show current filaments during high gain switching mode. Triggering of these devices with multiple fiber optics is demonstrated and the implications for high average current density switching are discussed. Switch jitter with high field lateral PCSS has been tested and its impact on multi-switch systems is explored. Results from high repetition rate device lifetime testing are also reported. Lateral switches with several types of contacts (including: refractory metallizations, diffused and ion-implanted Ohmic layers) have been fabricated and tested. Switch characteristics and lifetime results are discussed for each of these fabrication schemes. DOE

STABILITY AND DYNAMICS OF SPATIO-TEMPORAL STRUCTURES
H. Riecke Mar. 1993 7 p
(Contract DE-FG02-92ER-14303)
(DE93-011374; DOE/ER-14303/1) Avail: CASI HC A02/MF A01

The main goal of the project supported in this grant is to contribute to the understanding of localized spatial and spatio-temporal structures far from thermodynamic equilibrium. Here we report on our progress in the study of two classes of systems. We have started to investigate localized wave-pulses in binary-mixture convection. This work is based on our recently derived extension of the conventionally used complex Ginzburg-Landau equations. We are considering three regimes: dispersion-less supercritical waves; strongly dispersive subcritical waves; and localized waves as bound states of fronts between dispersionless subcritical waves and the motionless conductive state. We have completed our investigation of steady domain structures in which domains of structures with different wave numbers alternate, separated by domain walls. In particular, we have studied their regimes of existence and stability within the framework of a Ginzburg-Landau equation and have compared it to previous results. Those were based on a long-wavelength approximation, which misses certain aspects which turn out to be important for the stability of the domain structures in realistic situations. In addition, we give a description of our work on resonantly forced waves in two-dimensional anisotropic systems. DOE

HIGHLY ANISOTROPIC BUT NODELESS GAP FROM A VALENCE-FLUCTUATION PAIRING MECHANISM
B. H. Brandow 1993 5 p Presented at the Conference on Spectroscopies in Novel Superconductors, Santa Fe, NM, 17-19 Mar. 1993
(Contract W-7405-eng-36)
(DE93-010738; LA-UR-93-1088; CONF-930367-1) Avail: CASI HC A01/MF A01

We have refined and quantitatively explored a valence-fluctuation pairing mechanism, the finite-U mechanism introduced by Newns. This can provide an s-like (nodeless) gap. We use an Anderson-lattice Hamiltonian, with realistic parameter values derived from photoemission and BIS data. The Landau-Luttinger quasiparticle spectrum and the pairing interaction are obtained from a many-body variational formalism. Adequate pairing attraction is obtained, together with band narrowing (mass enhancement) and an extremely short coherence length, in reasonable agreement with experiment. These fully self-consistent results were obtained with an isotropic approximation to the band structure of a single CuO2 plane. Now, using a simplified treatment for a more realistic band structure, we find that the gap has strong in-plane anisotropy, although, it should probably still remain nodeless. This conclusion is consistent with a variety of data. DOE

AN ELLIPSOMETRY INVESTIGATION OF NUCLEATION AND GROWTH OF ELECTRON CYCLOTRON RESONANCE PLASMA DEPOSITED SILICON FILMS

M. Li, Y. Z. Hu, J. Wall, K. Conrad, and E. A. Irene 4 May 1993 17 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-89-J-1178)
(AD-A265037; TR-58) Avail: CASI HC A03

The nucleation and initial growth of Si films is fundamental to the understanding and control of rapid thermal CVD, RTCVD, and plasma enhanced CVD, PECVD processes. Herein we report on the nucleation and growth of Si deposited on oxidized silicon wafers by ECR PECVD in 600-700 C temperature range, under low-pressures, and using both in situ spectroscopic ellipsometry (SE) and single wavelength real-time ellipsometry. An island growth and coalescence model is used to interpret the real-time ellipsometry data. Initial nuclei distance and growth-parameters are derived. Atomic Force Microscopy (AFM) was used to observe the early stage of nucleation. In situ spectroscopic ellipsometry is used to measure the final Si film thicknesses and optical properties. The structure of the deposited crystalline Si films were characterized by XTEM. DTIC

SOLID-STATE STRUCTURES OF GUANIDINIUM METHANE, ETHANE, AND TRIFLUOROMETHANESULFONATE Technical Report, 1 Jun. 1992 - 31 May 1993
V. A. Russell, M C. Etter, and M D. Ward 22 Apr. 1993 7 p
(Contract N00014-89-J-1301)
(AD-A265293; TR-20-ONR) Avail: CASI HC A02/MF A01

The solid-state structures of guanidinium sulfonates, C(NH2)3(+)RSO3(-), are being studied, and the role of hydrogen bonding in controlling molecular packing is being assessed. We have found that guanidinium sulfonates frequently self-assemble into two-dimensional sheets formed by hydrogen bonds between the six guanidinium protons and the six sulfonate oxygen lone electron pairs. X-ray structures of guanidinium methanesulfonate, guanidinium ethanesulfonate, and guanidinium triflate are reported here. Each of these salts crystallizes in a bilayer structure of hydrogen-bonded sheets. DTIC

ON THE THEORY OF PHONORITON IN CUBIC SEMICONDUCTORS WITH A DEGENERATE VALENCE BAND
Nguyen Ai Viet (Institute of Theoretical Physics, Hanoi, Viet Nam.), Nguyen Thi Que Huong (Institute of Theoretical Physics, Hanoi, Viet Nam.), and Le Qui Thong (Hue Coll., Viet Nam.) Oct. 1992 13 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-613539; IC-92/320) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

The 'phonoriton' is an elementary excitation constructed from an exciton polariton and phonon in semiconductors under intense excitation by an electromagnetic wave near the exciton resonance. A theory of phonoriton in direct band gap cubic semiconductor with a degenerate valence band using the simple model of J.L. Birman and B.S. Wang is developed. In addition to experimental proofs of the existence of phonoriton, an experiment to measure its flight time is proposed. DOE

THE X RAY STANDING WAVES ON SURFACES
Hector D. Abruna 1993 20 p Sponsored in part by NSF and the Army Research Office
(AD-A265265) Avail: CASI HC A03/MF A01

The x-ray standing wave technique is a sensitive tool for determining the position of atoms within a crystal, adsorbed onto a surface or distributed within the crystal or at the interface. The technique is based on the x-ray standing wave field that arises as a result of the interference of coherently related incident and reflected plane waves and is described by the theory of dynamical diffraction of x-rays. When two coherently related traveling plane waves having the same wavelength pass through each other, their superposition results in a standing wave of period D = lambda/2 sin theta, where lambda is the wavelength of the traveling waves and 2 theta is the relative angle between them. The generation of a standing wave requires both an incident and a reflected wave, and the latter can be generated by either Bragg diffraction or total external reflection. DTIC

ADSORPTION AND DISSOCIATION OF DISILANE ON SI(001) STUDIED BY STM Interim Report, 1 Jun. 1992 - 31 May 1993
M. Bronikowski, Y. Wang, M. McEllistrem, D. Chen, and R. J. Hamers 18 May 1993 44 p
(Contract N00014-91-J-1629)
(AD-A265269) Avail: CASI HC A03/MF A01

The surface-adsorbed fragments resulting from the room-temperature adsorption and dissociation of disilane (Si2H6) on Si(001) are observed and identified using Scanning Tunneling Microscopy (STM). The predominant fragments are H and SiH2, which are identified by the symmetries of their binding sites on the surface. H atoms often bind near single or double dimer vacancy defects, while SiH2 tends to bind near C-type defects. We find that adsorbed H atoms induce buckling of the dimer rows on the Si(001) surface, while SiH2 groups do not. This difference is ascribed to differences in the electronic structure of the two surface-bound species. No systematic correlation between the positions of the H atom and SiH2 groups is evident, which indicates that the fragments of a single disilane molecule are not localized in a small region. This fact suggests that at least some of the molecular fragments from disilane dissociation are mobile on the Si(001) surface at room temperature. Further decomposition of the SiH2 fragments can be induced by annealing, which produces surface structures similar to those seen in molecular-beam epitaxial growth of silicon; small asymmetric islands form with low disilane coverages, whereas higher coverages give multilayer island growth. DTIC

(Contract N00014-89-J-1301)
(AD-A265294; TR-23-0NR) Avail: CASI HC A02/MF A01

Hydrogen bonding is used to direct guanidinium sulfonates, C(NH2)3(+)RSO3(-), into specific molecular packing arrangements in the solid state. Guanidinium sulfonates frequently self-assemble into two-dimensional sheets formed by hydrogen bonds between the six guanidinium protons and the six sulfonate oxygen lone electron pairs. Guanidinium 4-biphenylsulfonate crystallizes hydrogen bonding patterns. Synthesis of these polymorphs and their characterization by FTIR spectroscopy and single crystal x-ray diffraction is reported. PROGRESS TOWARD ATOMIC LAYER EPITAXY OF DIAMOND: DIAMOND FILMS GROWN ONE LAYER AT A TIME
Roy Gat, Terttu I. Hukka, Robin E. Rawles, and Mark P. DEvelyn May 1993 5 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1550)
(AD-A265530; TR-16-ONR) Avail: CASI HC A01

Diamond would be the ultimate coating for many applications; it is the hardest material known, it is chemically inert in most environments, it has a thermal conductivity five times that of copper, and it is optically transparent from ultraviolet through the mid- and far-infrared. However, conventional CVD methods for diamond have important limitations: many substrates of interest cannot withstand the 500-1000 C temperatures commonly employed, and the typically low nucleation density generates films with large crystal grains and rough morphologies. We are developing a novel low-pressure method for atomic layer epitaxy of diamond which should enable high-quality film growth at modest temperatures with very high nucleation densities. The method uses alternating fluxes of halocarbon radicals and atomic hydrogen, generated by reaction with atomic fluorine. Under suitable conditions, carbonatom additions to the growing film and subsequent rehydrogenation of the surface should each be self-limiting reactions resulting in deposition of one atomic layer of diamond per cycle. To date we have obtained evidence for diamond growth at rates up to 0.1 microns/hr from continuous flows of hydrogen and CHCL3, CH4, or C2H2 at reactor pressures between 10(exp -4) and 10(exp -2) Torr. HIGH FREQUENCY BEHAVIOR OF LONG AND SMALL JUNCTIONS Final Report, 1 Dec. 1988 - 30 Nov. 1992
Orest G. Symko 6 May 1993 19 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0149-89)
(AD-A265670; AFOSR-93-0393TR) Avail: CASI HC A03

This research consisted of studies of the fundamentals and applications of long Josephson junctions and very small junctions, all fabricated out of NbN. We have developed technology for fabricating by reactive sputtering high quality long Josephson junctions with current densities of 100-1,000 A/sq cm. Such junctions were used for studies of giant steps on the 1-5 curve caused by fluxon pinning and of macroscopic quantum tunneling down to 15 mK. A new system, a long Josephson junction biased at Fiske steps, is presented for studies of Macroscopic Quantum Tunneling. Our results show applications of fluxons in long Josephson junctions for Fluxon Oscillator, Voltage Standard, and for observing Macroscopic Coherent Tunneling. We have also studied very small NbN junctions fabricated with a STM where single electron tunneling is observed. We were the first to present such tunneling at room temperature; this is important for several applications. Students and postdoctoral fellows were involved in this research. DTIC

ANALYSIS OF THE ECONOMICS OF DC ARC CVD DIAMOND Quarterly Report No. 1
1993 43 p
(Contract N00014-93-C-2044)
(AD-A265688) Avail: CASI HC A03/MF A01

From the research conducted to date, it appears that the cost today to produce 1,000 six-inch wafers, 1 mm thick, by DC arc deposition technology is $4,072/wafer. Of the six operations included in this analysis (substrate preparation, deposition, etching, polishing, metallizing, and inspection), the deposition step contributes the bulk of the cost (85%). The total cost of a finished substrate is dominated by the cost of equipment (30.6%) and materials (25%). High equipment costs are attributable to the low deposition rate and to the high capital investment for deposition equipment. High material costs are attributed to the lack of gas recycling and to the use of expensive high purity gases. DTIC

POLARONIC CHARGE SEPARATION IN MIXED-HALIDE MX SOLIDS Professional Paper
A. Saxena, A. R. Bishop, X. Z. Huang, and J. T. Gammel Apr. 1993 58 p Limited Reproducibility: Document partially illegible
(AD-A266073) Avail: CASI HC A04/MF A01

We have obtained clear evidence for photoinduced electron hole pair separation in mixed-halide, halogen-bridged transition metal (MX) chain solids. Resonance Raman experiments on doped and photoexcited single crystals of mixed-halide (M = Pt; X=Cl, Br, and I) complexes indicate charge separation; electron polarons preferentially locate on the PtBr segment while hole polarons are trapped within PtCl segments. This polaron selectivity, which is potentially very useful for photovoltaic device applications, is demonstrated within theoretical calculations based on a discrete, 3/4-filled, two-band, tight-binding, extended Peierls-Hubbard model showing strong hybridization of PtCl and PtBr electronic bands as the driving force for separation. In contrast to PtCl(x)Br(1-x), the PtCl(x)I(1-x) system exhibits qualitatively different behavior such as 'self doping.' DTIC

SYNTHESIS AND MAGNETIC PROPERTIES OF NOVEL La*2-x*M*x*CuO*4 EQUALS Y* COMPOSITIONS (La EQUALS La, Pr, Nd, Sm, Eu, Cd; M EQUALS Ca, Sr, Ba; O (LESS THAN OR EQUAL) x 0.2; -0.5 (LESS THAN OR EQUAL) y (LESS THAN OR EQUAL) 0.5)
Jin Hyung Cho 1 Mar. 1993 142 p
(Contract W-7405-eng-82)
(DE93-011359; IS-T-1536) Avail: CASI HC A07/MF A02

Ln2CuO4 undergo transitions to reduced Ln2CuO(4-d) (Ln = La, d = 1/3; Ln = Pr, Nd, Sm, Eu, Gd, d = 1/2). The Nd2CuO4-type (T'-phase) La2CuO(4+d) is observed after reoxidation of La2CuO(3.67) below 500 C. The magnetic properties of T/O (K2NiF4-type) La2CuO4 behaves differently compared with solid-state-reacted La2CuO4. The implications of these nonsuperconducting behaviors within superconducting carrier densities are discussed from a structural point of view. La(2-x)M(x)CuO(4+d) (M = Ca, Sr; x = 0.05, 0.15), synthesized by low temperature route, also contain excess O. La-139 NQR of nonsuperconducting La(1.85)Sr(0.15)CuO(4.04) show metallic properties. Tolerance factor, based on ionic radii, is to describe structures of K2NiF4 related cuprates. With anisotropic thermal motions of apical O in La2CuO4, we discuss the role of out-of-plane O for stabilization of cuprate structures. The magnetic phase diagram and phase separation of La(2-x)Sr(x)CuO(4+delta) system (0.000 less than or equal to x less than or equal to 0.030, 0.0 less than or equal to delta) are reported. From the decrease of T(sub c) by doping we infer localization and pair-breaking induced by doped holes. Phase separation is realized with antiferromagnetism. We also observe scaling properties of susceptibilities versus renormalized temperatures and infer the finite size effects by doped holes. La-139 NQR spin-lattice relaxation are presented for La(2-x)Sr(x)CuO(4), x = 0.02 to 0.08. The rate below approximately 2T(sub N)(x) shows a power-law critical behavior while above it, the rate is exponential with a small x-dependent spin-stiffness constant. The spin-lattice relaxation arises from fluctuations of staggered magnetization in locally ordered mesoscopic domains. Magnetically ordered state is not a conventional spin glass. DOE

EXAMINATION OF THE SURFACE SECOND HARMONIC RESPONSE AT INFRARED WAVELENGTHS Technical Report, May 1992 - May 1993
E. K. Wong and G. L. Richmond 27 May 1993 28 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-89-J-1261)
(AD-A265206; TR-1) Avail: CASI HC A03

Contributing factors to the second harmonic response from Ag(111) and Au(111) surfaces have been examined in the long wavelength limit where nonresonant conditions prevail. The rotational anisotropy in the nonlinear response is found to persist for both metals in the absence of surface resonances and to show convergent behavior in both the relative phase and intensity as the incident energy is lowered from resonant to nonresonant conditions. The phase difference between the in-plane and out-of-plane response in the long wavelength limit can be described by linear Fresnel theory. Whereas the tensor elements corresponding to the out-of-plane response are found to dominate, the in-plane contributions are found to be non-negligible. DTIC

DEVELOPMENT OF ULTRA-LOW NOISE, HIGH SENSITIVITY PLANAR METAL GRATING COUPLED 3 TO 5 MULTIQUANTUM WELL INFRARED DETECTORS FOR FOCAL PLANE ARRAY STARING IR SENSOR SYSTEMS Quarterly Progress Report No. 7
Shang S. Li 1 May 1993 72 p
(Contract N00014-91-J-1976)
(AD-A265599) Avail: CASI HC A04/MF A01

During this reporting period, we have continued to make progress towards the program goals. We have designed, fabricated, and characterized several new types of 2-D metal grating coupled n-type GaAs/AlGaAs, AlAS/AlGaAs, InAlAs/InGaAs, and InGaP/GaAs QWIPs for 2-14 microns focal plane arrays (FPAs) staring infrared sensor applications. In addition, a new normal incidence two-color p-type strained layer InGaAs/InAlAs QWIP has been developed for the first time with the highest detectivity and low dark current reported for a p-type QWIP. Specific tasks performed during this period include the following: (1) design, growth, and fabrication of a new normal incidence p-type strained InGaAs/InAlAs QWIP grown on InP substrate by MBE technique; (2) completed theoretical and experimental studies of four dual mod operation QWIPs fabricated from n-type GaAs/AlGaAs, InGaAs/InAlAs, and AlAs/AlGaAs material systems; (3) completed theoretical and experimental studies of a type-2 AlAs/AlGaAs QWIP; (4) developed a new 2-D square mesh metal grating coupled structure for an InAlAs/InGaAs BTM QWIP with significant improvement in detector's responsivity and detectivity; (5) performed noise characterization on the InGaAs/InAlAs QWIP and identified the noise sources in this QWIP; and (6) completed numerical simulations of coupling quantum efficiency versus grating periodicity and grating dimension for a 2-D square mesh metal grating coupler formed on both the standard and BTM QWIP's. THE EFFECTS OF ORGANIC ADSORBATES ON THE UNDERPOTENTIAL DEPOSITION OF SILVER ON Pt(111) ELECTRODES
D. L. Taylor and H. D. Abruna 1993 31 p
(AD-A265623) Avail: CASI HC A03/MF A01

Studies have been undertaken to determine the effects of competing organic adsorbates on the underpotential deposition of silver on Pt(111). The adsorbates studied are known to bind to Pt primarily through the hetero-atom (either nitrogen or sulfur) and include pyrazine, 2,2'-bipyridyl, 4,4'-bipyridyl, 4-phenylpyridine, 1,2-Bis(4-pyridyl)ethane, 2-mercaptopyridine, and 4-mercaptopyridine. The effects of the adsorbate layer on silver deposition are strongly dependent on the nature and structure of the co-adsorbed species. Adsorbates that bind primarily through a ring nitrogen atom were found to inhibit the deposition of the second, but not the first, silver monolayer. This may be explained by the formation of a Pt(111)/Ag/adsorbate structure in which the silver deposits underneath the adsorbate layer. These adsorbates also displayed a significant pH dependence likely due to protonation of the binding atom. In contrast, the sulfur-containing adsorbates inhibited all deposition processes at the electrode surface except that of bulk silver deposition. In this case there was a significant overpotential to bulk deposition. Moreover, a monolayer of electrodeposited silver could be displaced from the Pt surface upon exposure of the electrode to a solution of 2-mercaptopyridine. This behavior would indicate a higher bond strength between the sulfur atom and the Pt surface than that between the ring nitrogens and the Pt surface. These results are consistent with the expected strengths of adsorption. DTIC

ELECTRODE POTENTIAL-INDUCED RECONSTRUCTION OF Au(100): EFFECT OF CHEMISORPTION ON NANOSCALE DYNAMICS AS PROBED BY THE IN-SITU SCANNING TUNNELING MICROSCOPY
Xiaoping Gao and Michael J. Weaver Apr. 1993 21 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1409)
(AD-A265900) Avail: CASI HC A03

The effect of iodide chemisorption on the nanoscale real-space dynamics associated with the electrode potential-induced formation and removal of the hexagonal reconstruction on Au(100) in aqueous solution was examined by means of in-situ scanning tunneling microscopy under potentiodynamic conditions. Unlike in 'non-adsorbing' media such as perchloric acid where the (1 x 1) yields (hex) phase change is slow (T(sub 1/2) is approximately 10 min), requiring adatom diffusion from terrace edges, the potential-induced transition in iodide can be remarkably rapid (less than 0.2 s). The latter features facile large-scale (ca 10-20 nm) gold mass transport emanating from former (1 x 1) terraces as well as from terrace edges. The likely roles of chemisorption in inducing such remarkably rapid reconstruction are briefly discussed. Author (DTIC)

SPATIAL LIGHT MODULATOR HAVING PHOTOSENSITIVE AND FERROELECTRIC LAYERS Patent Application
Tak-Kin Chu, inventor (to Navy) 22 Jan. 1993 9 p
(AD-D015731; US-Patent-Appl-SN-007884; Navy-Case-74662) Avail: CASI HC A02/MF A01

A spatial light modulator is optically addressable by exposure of a vitreous selenium layer to illumination of a write beam through a transparent electrode film, thereby establishing an electrically conductive path from a voltage source to a ferroelectric liquid crystal layer in contact with conductive reflector elements arranged in a pixel pattern. Changes in polarization of the ferroelectric layer are detected by means of a read beam transmitted there through to the reflector elements for reflection and exit from another transparent electrode film through which the read beam is applied. We report on the measurement of the diffusion length damage coefficient (K(sub L)) and the annealing characteristics of the minority carrier diffusion length (L(sub n)) in Czochralski-grown zinc-doped indium phosphide (InP), with a carrier concentration of 1 x 10(exp I8) cm(exp -3). In measuring K(sub L) irradiations were made with 0.5 MeV protons with fluences ranging from 1 x 10(exp 11) to 3 x 10(exp 13) cm(exp -2). Pre- and post-irradiation electron-beam induced current (EBIC) measurements allowed for the extraction of L(sub n) from which K(sub L) was determined. In studying the annealing characteristics of L(sub n) irradiations were made with 2 MeV protons with fluence of 5 x 10(exp 13) cm(exp -2). Post-irradiation studies of L(sub n) with time at room temperature, and with minority carrier photoinjection and forward-bias injection were carried out. The results showed that recovery under Air Mass Zero (AMO) photoinjection was complete. L(sub n) was also found to recover under forward-bias injection, where recovery was found to depend on the value of the injection current. However, no recovery of L(sub n) after proton irradiation was observed with time at room temperature, in contrast to the behavior of 1 MeV electron-irradiated InP solar cells reported previously. ENGINEERING SOLID-STATE MATERIALS. STRATEGIES FOR MODELING AND PACKING CONTROL OF MOLECULAR ASSEMBLIES INTO 3-D NETWORKS Technical Report, 1 Jun. 1992 - 31 May 1993
V. Videnova-Adrabinska, M C. Etter, and M. D. Ward 22 Apr. 1993 16 p
(Contract N00014-89-J-1301)
(AD-A265291; TR-22-ONR) Avail: CASI HC A03/MF A01

The crystal structure and properties of a number of urea cocrystals are studied with regard to symmetry of the hydrogen-bonded molecular assemblies. The logical consequences of hydrogen bonding interactions are followed step-by-step. The problems of aggregate formation, nucleation, and crystal growth are also elucidated. Endeavor is made to envisage the 2-D and 3-D hydrogen bond network in a manageable way by exploiting graph set short hand. Strategies of how to control the symmetry of molecular packing are still to be elaborated. In our strategy, the programmed self-assembly has been based on the principle of molecular recognition of self- and hetero-complementary functional groups. However, the main focus for pre-organizational control has been put on the two-fold axis estimator of the urea molecule. DTIC

(AD-A265685) Avail: CASI HC A02/MF A01

The main objective of the Institute was to bring together scientists from different fields of research such as semiconductors, oxides, and metallic materials, as well as those working on the development of systems for thin film processing and characterization. The highly interdisciplinary nature of the Institute allowed participant scientists to interchange ideas in an environment rarely available in other international conferences. This has opened a window of opportunity for collaboration in research and development, which will continue to require interdisciplinary exchange of ideas. DTIC

DEFORMATION MECHANISMS IN TUNGSTEN SINGLE CRYSTALS IN BALLISTIC IMPACT EXPERIMENTS Final Report, 1 Oct. 1991 - 30 Sep. 1992
W. J. Bruchey, Jr., R. N. Herring, P. W. Kingman, and E. J. Horwath May 1993 32 p
(DA Proj. 1L1-62618-AH-80)

The performance of tungsten single crystals in ballistic impact varies strongly as a function of crystallographic orientation. The deformation structure of recovered single crystal rods fired in ballistic environments has been characterized by optical microscopy, SEM and TEM, and x-ray diffraction. The observed microstructures are varied and provide substantial insights into the factors governing the penetration and flow behavior under ballistic conditions. Crystallographic orientation influences the potential for developing shear which enhances material flow, and this enhancement ultimately maximizes the energy available for target penetration. Microstructural analysis elucidates the various mechanisms occuring during the flow process for single crystals of high-symmetry orientations, and suggests possible analogies between the penetration behavior of the tungsten single crystals and other materials. ELECTRONIC AND TOTAL ENERGY PROPERTIES OF TERNARY AND QUATERNARY SEMICONDUCTOR COMPOUNDS, ALLOYS AND SUPERLATTICES Final Technical Report, 1 Dec. 1988 - 10 Jan. 1992
Walter R. L. Lambrecht 28 Aug. 1992 6 p
(Grant NAG3-954)
(NASA-CR-192905; NAS 1.26:192905) Avail: CASI HC A02/MF A01

This proposal was mainly concerned with the theoretical study of semiconductor compounds, alloys, and superlattices of interest for photovoltaic applications. In the last year (1991) a study was devoted to metal/graphite bonding in relation to use of graphite fiber reinforcement of Cu for high thermal conductivity applications. The main research topics addressed during the full period of the grant are briefly described: studies of the In-Ga-As ternary system; band-offsets at common anion and InAs/GaSb/AlSb heterojunctions; alloy theory (cluster variation method); and Cu/graphite bonding. Most of the work was described more extensively in previous yearly reports and renewal applications and in publications. The last topic is described more fully in a separate report attached. A list of publications resulting directly from this grant or from other grants but related to this work and of conference presentations is given at the end. Author (revised)

CORROSION AND PASSIVATION OF HIGH TEMPERATURE SUPERCONDUCTORS Final Report, 1 Jul. 1988 - 30 Sep. 1990
Stanley Bruckenstein 20 Dec. 1992 36 p
(Contract N00014-88-K-0621)
(AD-A265402) Avail: CASI HC A03/MF A01

Silver and copper were deposited by electroless deposition upon YBa2Cu3O7 (bulk pieces and fibers). The electrical properties of these coated materials were determined by the four-point resistivity method. Good electrical contact between electroless silver layers and the YBa2Cu3O7 substrate could be attained. Copper was electrodeposited on an electroless silver layer which provided excellent environment protection to the underlying YBa2Cu3O7. The stability of YBa2Cu3O(6.5+x) powder in various aqueous and nonaqueous environments was studied. The time dependence of sample weight and oxygen content, x, were determined for the samples exposed to atmospheres saturated with concentrated ammonium hydroxide, glacial acetic acid, acetone, hexane, toluene, ethanol, and methanol. Little evidence for reaction was found for the latter five organic vapors, while substantial reaction was found for the first two vapors. YBa2Cu3O(6.5+x) powder was also suspended in deionized water and aqueous 1 molar solutions of NaCl, KCl, KNO3, and NaBr. The results suggest that the reaction is minimal and probably involves only the surface of the powder. DTIC

The initial cluster compound, Na(2y)Mo(6)S(8+y) py(sub x), was discovered by reacting Mo(6)Cl(12) with higher stoichiometries of sodium hydrosulfide and sodium butoxide in butanol/pyridine. This compound can subsequently undergo ligand exchange reactions to form a variety of cluster complexes. Single-crystal structure determinations are reported for the pyridine (py), piperidine (pip), and pyrrolidine (pyrr) complexes: triclinic Mo(6)S(8)(PY)(6) (center dot) 1.65py, cubic Mo(6)S(8)(py)(6) (center dot) 2py, Mo(6)S(8)(pip)(6) (center dot) 7pip, and Mo(6)S(8) (pyrr)(6) (center dot) 1pyrr. Delegation of the cluster complexes was explored. Direct heating under dynamic vacuum led to incomplete delegation. Reactions with tin and lead resulted in formation of corresponding Chevrel phase compounds along with MoS(2). Thermolysis reactions in the presence of flowing ammonia gas resulted in further delegation than was evidenced for reactions explored in vacuo. Solution reactions with strong acids were studied in an attempt to protonate the ligands and thus make them better leaving groups only limited success was achieved. A new preparative route was developed for ternary molybdenum sulfides. Cation exchange reactions with Na(2y)Mo(6)S(8+y)(MeOH)(x) were used to form the cobalt, tin, lead, and holmium compounds. Preliminary hydrodesulfurization studies on the sodium and cobalt compounds showed that they possess larger surface areas and thiophene conversion percentages than Chevrel phases, but a lower HDS rate. AHARONOV-BOHM EFFECT IN LUTTINGER LIQUID
F. V. Kusmartsev Oct. 1992 9 p
(DE93-613818; IC-92/311) Avail: CASI HC A02/MF A01 (US Sales Only)

We show that in the systems with the spin-charge separation the period of the Aharonov-Bohm oscillation becomes half of the flux quantum. The effect is related to the fact that for the creation of the holons (spinons) two electrons at least are needed. The effect is illustrated on the example of the Hubbard Hamiltonian with the aid of bosonization technique including topological numbers. The effect exists also in the Luttinger liquid on two chains. DOE

SOME NEW/OLD APPROACHES TO QCD
D. J. Gross Nov. 1992 20 p Presented at the STRINGS 1992, Rome, Italy, 2-8 Sep. 1992
(Contract DE-AC03-76SF-00098)
(DE93-010451; LBL-33232; CONF-9209333-1) Avail: CASI HC A03/MF A01

In this lecture I shall discuss recent attempts to revive some old ideas to address the problem of solving QCD. I believe that it is timely to return to this problem which has been woefully neglected for the last decade. QCD is a permanent part of the theoretical landscape and eventually we will have to develop analytic tools for dealing with the theory in the infrared. Lattice techniques are useful but they have not yet lived up to their promise. Even if one manages to derive the hadronic spectrum numerically, to an accuracy of 10% or even 1%, we will not be truly satisfied unless we have some analytic understanding of the results. Also, lattice Monte-Carlo methods can only be used to answer a small set of questions. Many issues of great conceptual and practical interest--in particular the calculation of scattering amplitudes--are thus far beyond lattice control. Any progress in controlling QCD in an explicit, analytic fashion would be of great conceptual value. It would also be of great practical aid to experimentalists, who must use rather ad-hoc and primitive models of QCD scattering amplitudes to estimate the backgrounds to interesting new physics. I will discuss an attempt to derive a string representation of QCD and a revival of the large N approach to QCD. Both of these ideas have a long history, many theorist-years have been devoted to their pursuit--so far with little success. I believe that it is time to try again. In part, this is because of the progress in the last few years in string theory. Our increased understanding of string theory should make the attempt to discover a stringy representation of QCD easier, and the methods explored in matrix models might be employed to study the large N limit of QCD. DOE

CANONICAL OPERATOR FORMULATION OF NONEQUILIBRIUM THERMODYNAMICS
M. Mehrafarin Sep. 1992 19 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-613028; IC-92/297) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

A formulation of nonequilibrium thermodynamics is proposed which emphasizes the fundamental role played by the Boltzmann constant k in fluctuations. The equivalence of this and the stochastic formulation is demonstrated. The k approaches 0 limit of this theory yields the classical deterministic description of nonequilibrium thermodynamics. The new formulation possesses unique features which bear two important results namely the thermodynamic uncertainty principle and the quantization of entropy production rate. Such a theory becomes indispensable whenever fluctuations play a significant role. DOE

A GROUP-THEORETIC APPROACH TO THE STUDY OF SMALL OSCILLATIONS OF A DYNAMICAL SYSTEM WITH A KNOWN SYMMETRY
G. C. Chukwumah Sep. 1992 17 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-612971; IC-92/304) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

By way of illustrating how group representations can be gainfully utilized in the study of oscillations of dynamical/mechanical systems with known symmetries, the oscillations of a simple dynamical system consisting of three identical masses with a triangular symmetry were studied. The particles are connected by light strings having the same stiffness constant. By use of irreducible representations of the symmetry group of the dynamical system, one obtains the frequencies of the normal modes of oscillation of the system without having to solve the characteristic equation of degree six in the eigenvalue of they system. This approach greatly simplifies the determination of the motion of the system and can easily be extended to other dynamical/mechanical problems with known symmetries. DOE

N94-10403 International Centre for Theoretical Physics, Trieste (Italy).
ON THERMODYNAMIC PROPERTIES OF HEAVY FERMION SYSTEMS IN MAGNETIC FIELD
Chen-Chung Lee, Chun Chen, and Xu Wang (Nankai Univ., Tiangjin, China.) Oct. 1992 25 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-613819; IC-92/329) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

Using a two-conduction-band Anderson lattice model, the influence of magnetic fields on the thermodynamic properties of heavy fermion systems is studied by means of the slave boson mean-field theory. The depression of the heavy fermion state by magnetic fields is found. A theoretical explanation to the anomalous volume magneto-striction of heavy fermion systems is also given in this paper. DOE

EFFECTIVE ACTION IN THE GAUGED NAMBU-JONA-LASINIO MODEL
V. P. Gusynin and V. A. Miranskij 1991 28 p In RUSSIAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-617654; ITF-91-50) Avail: CASI HC A03 (US Sales Only)

The gauged Nambu-Jona-Lasinio (NJL) model which underlies the modern mechanisms of dynamical electroweak symmetry breaking, without fundamental Higgs fields, is investigated. Using the approach based on the formalism of Green's functions of composite operators, the low energy effective action of the gauged NJL model is derived as a series in powers of the derivatives of composite fields. The explicit expression of the effective action in the case of weak (alpha much less than 1) gauge interaction is obtained. The structure of the effective action, with respect to scale transformation, is established in the whole region with alpha less than or equal to alpha(sub c) = pi/3. DOE

ON RENORMALIZATION GROUP FLOW IN MATRIX MODEL
H. B. Gao Oct. 1992 5 p
(DE93-613050; IC-92/302; ZIMP-92-18) Avail: CASI HC A01/MF A01 (US Sales Only)

The renormalization group flow recently found by Brezin and Zinn-Justin by integrating out redundant entries of the (N+1) x (N+1) Hermitian random matrix is studied. By introducing explicitly the RG flow parameter, and adding suitable counter terms to the matrix potential of the one matrix model, we deduce some interesting properties of the RG trajectories. In particular, the string equation for the general massive model interpolating between the UV and IR fixed points turns out to be a consequence of RG flow. An ambiguity in the UV region of the RG trajectory is remarked to be related to the large order behavior of the one matrix model. DOE

INTERFEROMETRY WITH PARTICLES OF NON-ZERO REST MASS
G. I. Opat 1992 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-613518; UM-P-92/57) Avail: CASI HC A03 (US Sales Only)

Interferometry as a space-time process is described. Starting from this viewpoint, a convenient formalism for the phase shifts which arise in particle interferometry is developed. This formalism is based on a covariant form of Hamilton's action principle and Lagrange's equations of motion. It is shown that this Lorentz invariant formalism yields a simple perturbation-theoretic expression for the general phase shift that arises in matter wave interferometry. The resulting formalism will be used to analyse the Sagnac effect, gravitational field measurements, and several Aharonov-Bohm-like topological phase shifts. DOE

FROM THE WEYL THEORY TO A THEORY OF LOCALLY ANISOTROPIC SPACE-TIME
G. Y. Bogoslovsky 1991 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE92-644734; INP-MSU-91-15-219; NIIYaF-MGU-91-15-219) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

It is shown that Weyl ideas, pertaining to local conformal invariance, find natural embodiment within the framework of a relativistic theory based on a viable Finslerian model of space-time. This is associated with the peculiar property of the conformal invariant Finslerian metric which describes a locally anisotropic space of events. The local conformal transformations of the Riemannian metric tensor leave invariant rest masses as well as all observables and thus, appear as local gauge transformations. The corresponding Finslerian theory of gravitation turns out, as a result, to be an Abelian gauge theory. It satisfies the principle of correspondence with Einstein theory and predicts a number of nontrivial physical effects accessible for experimental test under laboratory conditions. DOE

PLANCK SCALE EFFECTS ON THE MAJORON
E. Kh. Akhmedov, Z. G. Berezhiani (Muenster Univ., Germany.), R. N. Mohapatra (Maryland Univ., College Park.), and G. Senjanovic Oct. 1992 11 p
(DE93-613120; IC-92/328; UMDHEP-93-020; LMU-12/92; SISSA-149/92/EP) Avail: CASI HC A03/MF A01 (US Sales Only)

The hypothesis that non-perturbative gravitational effects lead to explicit breaking of global symmetries is considered in the context of Majoron models. We find that the nonvanishing Majoron mass generated by these effects can overclose the universe unless the massive Majoron is unstable. The cosmological mass density constraints can then be satisfied only if V(sub BL) less than 10 TeV, where V(sub BL) is the scale of B - L symmetry breaking. DOE

N94-10631# International Centre for Theoretical Physics, Trieste (Italy).
A LATTICE GAS MODEL FOR ENZYME KINETICS WITH NEXT-NEAREST NEIGHBOR INTERACTIONS
R. Mejdani, A. Gashi (Tirana Univ., Albania.), and M. Ifti (Tirana Univ., Albania.) Sep. 1992 12 p
(DE93-613026; IC-92/280) Avail: CASI HC A03/MF A01 (US Sales Only)

It is shown that, by using a one-dimensional lattice gas model with the next-nearest neighbor interactions and calculating the thermodynamic potential of the system by means of the transfer matrix method, we can find numerically for enzyme kinetics some new diagrams of saturation curve. These diagrams in the limit of no interactions between sites reduce to the classical Michaelis-Henri diagrams and in the limit of the nearest neighbor interactions to some other diagrams which we have obtained before by using a correlated walks theory. These new diagrams of saturation curve can be useful for the experimental investigation. DOE

QUASI-RELATIVISTIC EFFECTS IN BARRIER-PENETRATION PROCESSES
D. V. Anchishkin 1991 23 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-617730; ITP-91-18) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

The problem of a particle tunneling through a potential barrier is solved within the quasi-relativistic Schroedinger equation. It is shown that the relativistic effects of the subcarrier add significantly tothe penetration coefficient when some relations between the parameters of the barrier and the mass of a tunneling particle are satisfied. An account of these effects for the penetration of low energy pi(+)-mesons through the Coulomb barrier of a U-298 nuclei yields an increase in penetration coefficient of 30 percent as compared to the nonrelativistic one. Also, we give the criteria in which the contribution of the 'under-barrier relativism' to the penetration coefficient becomes essential. DOE

GENERALIZED SPIN SYSTEMS AND SIGMA-MODELS
S. RandjbarDaemi, A. Salam, and J. Strathdee Sep. 1992 35 p Limited Reproducibility: More than 20% of this document may be affected by

microfiche quality
(DE93-613981; IC-92/294) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

A generalization of the SU(2)-spin systems on a lattice and their continuum limit to an arbitrary compact group G is discussed. The continuum limits are, in general, non-relativistic (sigma)-model type field theories targeted on a homogeneous space G/H, where H contains the maximal torus of G. In the ferromagnetic case the equations of motion derived from our continuum Lagrangian generalize the Landau-Lifshitz equations with quadratic dispersion relation for small wave vectors. In the antiferromagnetic case the dispersion law is always linear in the long wavelength limit. The models become relativistic only when G/H is a symmetric space. Also discussed are a generalization of the Holstein-Primakoff representation of the SU(N) algebra, the topological term, and the existence of the instanton type solutions in the continuum limit of the antiferromagnetic systems. DOE

QUANTUM DYNAMICS OF HELIUM CLUSTERS Final Report, Mar. 1989 - Mar. 1993
K. B. Whaley Mar. 1993 44 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-89-J-1755)
(AD-A266060) Avail: CASI HC A03

Our study of helium clusters was motivated by the desire to understand the scaling of the unusual properties of bulk He-4, a quantum liquid, in finite size systems as one goes from the macroscopic regime to the regime of molecular dimensions. This is fully in the spirit of general cluster research, namely to develop our understanding of how the transition from molecular to bulk systems (or vice versa) is reflected in the internal structure and dynamics of finite size aggregates. The unique feature of helium is its dominant quantum behavior, resulting from a low mass and weak interatomic binding energy. Clusters of helium are therefore very weakly bound van der Waals species, whose properties were expected to be dominated by zero point delocalization effects. During this grant period, we devoted our attention exclusively to clusters of He-4, which are bose systems. These are more strongly bound than the fermionic species He-3(sub N), and are also easier and cheaper to study experimentally. Furthermore, analogy with the bulk behavior suggests that any superfluid effects if present will occur at considerably higher and therefore experimentally more readily accessible temperatures for the He-4 species. In addition to the helium clusters, we also applied our Monte Carlo techniques to clusters of molecular hydrogen, which for J = 0 are also Bose clusters. These are more strongly bound than clusters of helium, yet are still very delocalized by chemical standards and offer an intriguing possibility for a new superfluid. DTIC

Starting from free relativistic particles whose position and velocity can only be measured to a precision less than Delta(r)Delta(v) greater than equivalent to (+/-)k/2 sq m/s, we use the relativistic conservation laws to define the relative motion of the coordinate r = r(sub 1) - r(sub 2) of two particles of mass m(sub 1), m(sub 2), and relative velocity v = Beta(c) = k(sub 1) - k(sub 2)/k(sub 1) + k(sub 2) in terms of conic section equation v(exp 2) = Gamma(2/r +/- 1/a) where '+' corresponds to hyperbolic

and '-' to elliptical trajectories. The equation is quantized by expressing Kepler's Second Law as conservation of angular momentum per unit mass in units of k. In a sense, we obtain 'spin' from this quantization. Since (Gamma)/a cannot reach c(exp 2) without predicting either circular or asymptotic velocities equal to the limiting velocity for particulate motion, we can also quantize velocities in terms of the principle quantum number.

COSMOLOGICAL RESTRICTIONS ON CONFORMALLY-INVARIANT SU(5) GUT MODELS
G. Esposito, G. Miele (Istituto Nazionale di Fisica Nucleare, Naples, Italy.), and L. Rosa (Istituto Nazionale di Fisica Nucleare, Naples, Italy.) Nov. 1992 26 p
(DE93-619770; IC-92/387) Avail: CASI HC A03/MF A01 (US Sales Only)

Dirac's theory of constrained Hamiltonian systems is applied to the minimal conformally-invariant SU(5) grand-unified model studied at 1-loop level in a de Sitter universe. For this model, which represents a simple and interesting example of GUT theory and at the same time is a step towards theories with large gauge group like SO(10), second-class constraints in the Euclidean-time regime exist. In particular, they enable one to prove that, to be consistent with the experimentally established electroweak standard model and with inflationary cosmology, the residual gauge-symmetry group of the early universe, during the whole de Sitter era, is bound to be SU(3)xSU(2)xU(1). Moreover, the numerical solution of the field equations subject to second-class constraints is obtained. This confirms the existence of a sufficiently long de Sitter phase of the early universe, in agreement with the initial assumptions.

NON-BARRIER TUNNELING IN PRESENCE OF DISSIPATIONS [TUNNELIROVANIE BEZ BA'ERA PRI DISSIPATSII]
S. M. Latinskij 1992 12 p In RUSSIAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-621381; KFTI-92-6) Avail: CASI HC A03 (US Sales Only)

The influence of dissipation on the interaction between classical and tunneling mechanisms removing a system from metastable state was investigated. It was shown that, depending upon the potential parameters, such a removal in the presence of dissipation may be suppressed either on classical or on tunneling trajectories. In its turn, a strong dissipation always suppresses the tunneling mechanism.

GREEN-SCHWARZ SUPERSTRINGS IN THE GENERALIZED HARMONICAL NEWMANN-PENROSE FORMALISM
I. A. Bandos and A. A. Zheltukhin 1991 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-621422; KFTI-91-46) Avail: CASI HC A03 (US Sales Only)

Green-Schwarz superstring theory in $D = 4$ and 10 is formulated in an extended space including additional spinor coordinates of the Cartesian moving frame. These spinor coordinates, which are realized in the form of the Lorentz harmonics, are used for the construction of covariant irreducible generators of fermionic H-symmetry. The generalizations of this Lorentz harmonical superstring formulation to the case of super-p-branes with p greater than 1 (including supermembranes $p = 2$) are discussed shortly.

SIMILARITY OF THE LEADING CONTRIBUTIONS TO THE SELF-ENERGY AND THE THERMODYNAMICS IN TWO- AND THREE-DIMENSIONAL FERMI LIQUIDS
D. Coffey and K. S. Bedell 1993 5 p Presented at the Conference on Spectroscopies in Novel Superconductors, Santa Fe, NM, 17-19 Mar. 1993
(Contract W-7405-eng-36)
(DE93-012673; LA-UR-93-1414; CONF-930367-4) Avail: CASI HC A01/MF A01

We compare the self-energy and entropy of a two- and three-dimensional Fermi Liquids (FL's) using a model with a contact interaction between fermions. For a two-dimensional (2D) FL we find that there are T(exp 2) contributions to the entropy from interactions separate from those due to the collective modes. These T(sup 2) contributions arise from nonanalytic corrections to the real part of the self-energy and are analogous to T(exp 3)lnT contributions present in the entropy of a three-dimensional (3D) FL. The difference between the 2D and 3D results arises solely from the different phase space factors.

SWIRL AS A MEANS OF LIQUID MANAGEMENT IN LOW GRAVITY
W. Gene Steward Aug. 1993 22 p
(NASA Order A-41524-C)
(NASA-CR-4545; A-93116; NAS 1.26:4545) Avail: CASI HC A03/MF A01

Swirling of a liquid in a container may prove to be a more desirable method of managing liquids in low gravity (space) environments than by rotating the entire container. By injecting a relatively high velocity liquid tangentially into the body of the fluid, swirl can best be started rapidly, however an estimate of the quantity and velocity of jetflow, or mechanical power of a pump impeller required to maintain a given radial acceleration (G force) is needed to assess the feasibility of such a method. While the key aspect of the problem is determining the rate of rotational energy dissipation by wall friction in the container, there are other considerations, and the present study investigates the possible additional effects of axial variation of tangential velocity and secondary (radial and axial) flow components within the rotating fluid. NEW TESTS OF THE EQUIVALENCE PRINCIPLE USING NON-METRIC COUPLINGS OF ELECTROMAGNETISM AND GRAVITATION Ph.D. Thesis
Jody Hupton Palmer 1992 141 p
Avail: Univ. Microfilms Order No. DANN72425

Calculations are performed for the physical predictions made by theories of gravity that introduce non-metric couplings of gravitation to electromagnetism. These results are then compared with existing observations in order to place limits on the viability of describing the solar gravitational field by theories that employ an Algebraically Extended (AE) metric in the gravitational field equations. The prototypical AE theory used in these calculations is Moffat's Nonsymmetric Gravitation Theory (NGT). It is shown that a class of AE theories of gravity, which includes NGT, using a particular general form of coupling, predicts a polarization dependent speed of light. This leads directly to polarization dependent bending of light (gravitationally induced birefringence) and radar echo time delay. It also leads to an orientation dependence of the energy of certain atomic transitions. Finally, the theory predicts an observed depolarization of solar spectral lines near the limb of the Sun. The theoretical maximum of observable circular polarization is compared with observations of Stokes V for certain spectral lines. This comparison is used to place limits on the NGT contributions to gravitational physics in the solar system. The limits are weakly dependent on a parameter involved in modeling of the solar atmosphere. A highly conservative model gives limits approximately 70 times stronger than previous limits. A model using the best available estimate of the solar modeling parameter gives a limit that is three orders of magnitude tighter than previous limits. Dissert. Abstr.

EXPLORATIONS IN QUANTUM GRAVITY: FROM ONE LOOP EFFECTIVE ACTIONS TO TWO-DIMENSIONAL THEORIES Ph.D. Thesis
Lev Tarasoff 1992 154 p
Avail: Univ. Microfilms Order No. DANN73737

Issues and approaches relating to the quantization of gravity are explored. The one-loop effective action of quantum gravity coupled to scalar fields in n dimensions is recalculated using a unique regulating scheme, operator regularization, that avoids all divergences. For the above case as well as for Chi(sup N)(sub 4) theory and quantum scalars on a curved background, non-renormalizability is shown to manifest itself in the presence of scale-dependent terms not present in the original Lagrangian. Thus non-renormalizability of quantum gravity need not be interpreted as uncontrollable divergences in the perturbative expansions. In this case, non-renormalizability indicates fundamental indeterminancies in the theory. Using the simple brick wall model of 't Hooft, the black hole horizon is seen to have a cutoff effect on quantum states of surrounding fields that is independent of the black hole charge and mass for all space time dimensions greater than 3. The issues around the breakdown of this result for 2 dimensions are also discussed. Two-dimensional (2D) modeling of gravity and quantum gravity is explored. First, black hole solutions of a 2D version of the Einstein field equations are discussed. Then, based on an action that allows couplings to matter fields, a fully covariant Hamiltonian analysis of the 2D gravity theory is carried out. An exact solution to the quantum constraints is obtained for the case of gravity coupled to electromagnetism. The results of the above studies support the thesis that non-renormalizability of quantum gravity is indicative of the inconsistency of applying perturbative quantum field theoretic methods to gravitational theory (i.e. general relativity). The brick wall model traces part of this incompatibility to the major role that the causal structure of spacetime plays in the dynamics of quantum fields. Current approaches to Quantum Field Theory generally rely on a fixed causal structure and therefore violate the integrity of general relativity. The 2D gravity theory is then shown to be a useful model for exploring the quantization of gravity. The calculational simplicity of the model and its similarity to (3 + 1) dimensional general relativity suggests that it will be useful in developing approaches to quantum gravity that do not require a fixed background structure. Dissert. Abstr.

ABSORPTION SPECTRUM CALCULATIONS USING MIXED QUANTUM-GAUSSIAN WAVE PACKET DYNAMICS Technical Report, 1 Jun. 1992 - 31 May 1993
K. Haug and H. Metiu 20 May 1993 44 p
(Contract N00014-90-J-1209)
(AD-A265179) Avail: CASI HC A03/MF A01

We calculate the absorption spectrum of a cluster using a computational method in which classical-like degrees of freedom for the nuclei are described by Gaussian wave packets while the valence electrons are treated quantum mechanically. We examine the spectral features in comparison to an even simpler mixed quantum-classical model in which the nuclear motion is treated by purely classical mechanics. Anomalous features (such as negative absorption) in the absorption spectrum which can arise from mixed quantum-classical methods are examined and the Gaussian wave packet nuclear dynamics is found to substantially reduce these anomalous features. This method is applied to a two-coordinate model problem in which exact numerical results can be obtained, and we find that the method works fairly well. We also apply the method to the valence electronic absorption spectrum for a KXe6 cluster. The method does not suffer from the dramatic failure seen when Xe motion is treated classically. The method is used to calculate the vibrational width and the vibrational structure of the electronic absorption spectrum. DTIC

ESTABLISHING BASELINE DATA FOR AN EXPERIMENTAL APPRATUS THAT MEASURES HEAT TRANSFER UNDER CONDITIONS OF OSCILLATING PRESSURE AND FLOW M.S. Thesis
Charles E. Dean May 1993 148 p Sponsored in part by Martin Marietta Energy Systems, Inc.
(Grant NAG3-1076)
(NASA-CR-193772; NAS 1.26:193772; AD-A265925) Avail: CASI HC A07/MF A02

Mathematical correlations for predicting heat transfer under conditions of oscillating pressure and flow are in their developmental infancy. Such heat transfer is commonly found in reciprocating machinery such as internal combustion engines, gas springs, and Stirling cycle engines. In order to understand and improve the thermodynamic performance of reciprocal engines, it is necessary that mathematical correlations be developed that accurately predict heat loss through the walls of the components within these systems. A heat transfer apparatus has been built that models the oscillating flow of a gas in a pipe as found in the regenerator of a Stirling engine. The apparatus is capable of measuring stream temperature and velocity at any point across the diameter of the pipe, the wall temperature, gas pressure, and gas to wall heat flux. This work addresses the collection of baseline heat transfer data for this apparatus under conditions of oscillating flow and pressure by (1) explaining the addition of a laser Doppler velocimeter to measure stream velocities, (2) investigating velocity profiles within the test section as the flow oscillates, and (3) recording and analyzing baseline heat transfer data. Results show a close correlation between the phase angle between the two compressors mounted at each end of the test section and the complex-valued Nusselt number that has been derived. DTIC

BOILING HEAT-TRANSFER PROCESSES AND THEIR APPLICATION IN THE COOLING OF HIGH HEAT FLUX DEVICES Final Report, Oct. 1990 - Oct. 1992
G. R. Beitel Jun. 1993 148 p
(AD-A266086; AEDC-TR-93-3) Avail: CASI HC A07/MF A02

Water cooling is used extensively at AEDC to prevent the failure of high-enthalpy arc heater components at elevated heat loads where cooling by radiation, conduction, and natural convection from air circulation are ineffective. Other cooling techniques such as the use of liquid metals, transpiration, or film cooling pose their own disadvantages or limitations and are certainly possibilities for providing cooling at much more severe heating conditions where water cooling alone may be inadequate. The current interest is in exploiting backside water cooling to the limit of its capability, especially for arc heater nozzles. Such an application requires an understanding of the parameters that affect the cooling processes and the determination of the limiting point where the surface fails due to inadequate cooling. This report reviews the different processes encountered in backside water cooling and identifies those processes that are desirable for effective cooling of high-enthalpy facility components; identifies those parameters which affect the cooling processes of interest and the trend of cooling performance when the parameters are individually varied; and presents a summary of applicable theoretical, analytical, and experimental work in surface cooling performed in the past 50 years. A SUMMER PROGRAM IN MATHEMATICS AND COMPUTER SCIENCE FOR ACADEMICALLY ORIENTED STUDENT Report, Jun. 11 - Jul. 1992
Bernis Barnes 24 Jul. 1992 164 p Sponsored by ONR Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A263467) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The 1992 UDC-Navy summer intervention program in mathematics and computer science for academically oriented students, as did the 1991 program, ranks among the most successful programs. The five-week intensive and rigorous academic program for the thirty-six mainly ninth and tenth grade students had a good mix of students from the public, private, and parochial schools of the D.C. area. As in the past ten years, the under-representation of minorities, especially Blacks and Hispanics, in engineering, natural science, and other mathematics-based fields was given a high priority. The students, most of whom are from the under-representative groups, had an opportunity to strengthen their background in mathematics and were encourage to pursue careers in mathematics-based fields. They also had an opportunity to increase their awareness of the many career opportunities that are available in mathematics-based fields and of the preparation that is necessary to pursue careers in these areas. The program faculty, which has had several years of experience in teaching local minority students, provided encouragement and motivation, as well as, a caring and supportive environment. DTIC

PROJECT TIMS (TEACHING INTEGRATED MATH/SCIENCE) Annual Report
Leo Edwards, Jr. 11 Jun. 1993 143 p
(Grant NAGw-3083)
(NASA-CR-194288; NAS 1.26:194288) Avail: CASI HC A07/MF A02

The goal of this project is to increase the scientific knowledge and appreciation bases and skills of pre-service and in-service middle school teachers, so as to impact positively on teaching, learning, and student retention. This report lists the objectives and summarizes the progress thus far. Included is the working draft of the TIMS (Teaching Integrated Math/Science) curriculum outline. Seven of the eight instructional subject-oriented modules are also included. The modules include informative materials and corresponding questions and educational activities in a textbook format. The subjects included here are the universe and stars; the sun and its place in the universe; our solar system; astronomical instruments and scientific measurements; the moon and eclipses; the earth's atmosphere: its nature and composition; and the earth: directions, time, and seasons. The module not included regards winds and circulation. CASI

ANALYSIS OF THE COST EVALUATION OF ESA PROGRAMMES AND COMPARABLE NATIONAL AND INTERNATIONAL PROGRAMMES Final Report
L. P. White, S. R. Dauncey, and R. T. Gibson Jun. 1992 141 p
(Contract ESA-9915/92/F/EM)
(GTS-92063) Copyright Avail: CASI HC A07/MF A02

The objective of the study is to investigate cost and cost trends of ESA programs and comparable national and international programs for the purpose of identifying cost over-runs and the reasons for these. As well as satellite programs, these include a selection of civil and military aircraft programs. The emphasis is on the main development phase in each case, though for the non-ESA programs the costs for these are usually less readily separable than is the case with ESA records. Derived from text

A COMPARISON OF HIGH AND LOW-IMPACT REPORTS OF INVESTIGATION ON ADJUDICATORS' DECISION MAKING: A PILOT STUDY
James E. Suchan Jan. 1993 58 p
(AD-A265747; PERS-93-002) Avail: CASI HC A04/MF A01

This report examines the effect of style of written communication on personnel security determinations. Forty senior adjudicators from four sites reviewed two cases containing significant derogatory information. The results indicate that format of the ROI did not affect the overall adjudication determination, but site-specific processes in reaching the decision were evident. A discussion is presented of outside-the-document factors that may affect readers' processing of written communications. DTIC

AN ADVISOR MODULE FOR TACTICAL AND STRATEGIC STATE-ORIENTED PLANNING SYSTEMS WITH AN APPLICATION IN MANPOWER PLANNING
H. Boers, W. Z. Venema, and J. Wessels (International Inst. for Applied Systems Analysis, Laxenburg, Austria.) Dec. 1992 30 p
(MEMO-COSOR-92-57; ETN-93-94331) Copyright Avail: CASI HC A03/MF A01

A user-controlled breath-first search method is discussed. The method is developed for generating qualitative and quantitative advice in tactical and strategic state oriented planning situations that are modeled with a network structure. A practical application in the field of manpower planning is demonstrated. The results show that the method can be implemented with little risk of combinatorial explosion. It is demonstrated that for some situations it is sensible to combine rule based with algorithmic approaches. ESA

NATIONAL AERO-SPACE PLANE: A NEED FOR PROGRAM DIRECTION AND FUNDING DECISIONS
Louis J. Rodrigues Jun. 1993 13 p
(GAO/NSIAD-93-207; B-235387) Avail: CASI HC A03/MF A01; GAO, PO Box 6015, Gaithersburg, MD 20877 HC

This report discusses the status of efforts to resolve the National Aero-Space Plane (NASP) Program's cost, schedule, and technical problems. The Program is a joint endeavor of the Department of Defense (DOD) and National Aeronautics and Space Administration (NASA) aimed at developing basic technology for future launch and hypersonic flight vehicles. The Program is currently in the second of three phases. Phase 1 evaluated the feasibility and technical concept for the aerospace plane. Phase 2, which ends in March 1994, is the technology development and maturation phase. Phase 3 involves designing, building, and testing the X-30. Funding constraints and technical concerns have caused DOD and NASA to reconsider the planned schedule. Additionally they have not achieved concensus on funding needs. The General Accounting Office recommends better management of the Program. In particular, GAO suggests that the Secretary of Defense and the NASA Administrator provide specific direction on the Program's long-term technical objectives and goals and that the Director, Office of Science and Technology Policy provide clear direction and guidance for the NASP Program. NASA PROCUREMENT: PROPOSED CHANGES TO THE JET PROPULSION LABORATORY CONTRACT. REPORT TO CONGRESSIONAL REQUESTERS
Jul. 1993 22 p
(GAO/NSIAD-93-178; B-253238) Avail: CASI HC A03/MF A01, GAO, PO Box 6015, Gaithersburg, MD 20877 HC

Selected provisions of the current contract for managing and performing research and development at the Jet Propulsion Laboratory (JPL) are discussed. JPL, a federally funded research and development center (FFRDC), is operated by the California Institute of Technology, and their next contract with the National Aeronautics and Space Administration (NASA) is being negotiated. In accordance with federal regulations, FFRDC's are operated by universities, other nonprofit organizations, or autonomous units of industrial firms. They are funded to meet specific long-term needs that cannot be met in any other way. The current contract's deviations from the Federal Acquisition Regulations (FAR) are mentioned; 27 were approved, but the new contract will likely have fewer. The Government Accounting Office recommends that JPL's scope of work be highly specific, be carefully reviewed, and that the contract state clearly that 'working meals' are an unallowable cost. NASA is advised to determine to what extent they should pay for college tuition for dependents of JPL employees. Advice on NASA fee-paying policies is also provided. CASI

FEDERAL CONTRACTORS IN APPALACHIA
R. F. Fullenbaum and M. A. McNeil Mar. 1993 92 p Sponsored by

Appalachian Regional Commission, Washington, DC
(Contract ARC-91-132-CO-10783-91-I-302-0)
(PB93-188779) Avail: CASI HC A05/MF A01

The research provides information on the characteristics of Appalachian small firms that have been successful in obtaining federal contract awards and suggests state policy initiatives that would likely be the most productive in stimulating the acquisition of federal contracts. The three groups studied for 1984, 1986, and 1988 are all small Appalachian federal contractors, women-owned small business contractors, and minority-owned small business contractors. Federal contractors in the United States are more likely to be divisions of larger sized firms; located in metropolitan areas; and focused on products and services such as nonresidential construction, some aspects of manufacturing, wholesale machinery and equipment, and miscellaneous business services. By comparison, the profile of the typical small Appalachian business is a single establishment with one to nine or 10 to 49 employees; only marginally more likely to be located in a metropolitan area; and more focused on retail trade, residential construction, and services such as hotel, motel, and auto repair. RESEARCH AND DEVELOPMENT OF POST-CLASSICAL MANAGEMENT TOOLS FOR GOVERNMENT PROGRAM OFFICES, VOLUME 2
H. A. Kurstedt and D. S. Sink Feb. 1993 309 p
(Contract DE-FG02-91NP-00119)
(DE93-010236; DOE/NP-00119/3-Vol-2) Avail: CASI HC A14/MF A03 (US Sales Only)

A critical link in the GSS model is documenting, experience - lessons teamed from cases of similar past and contemporary organizations, and the ongoing experience of the target organization. The primary purpose of this research area is to support the development of a process by which managers of large complex programs can access information from research literature, from past cases, and especially from organizational experience to adapt planned strategy to meet future demands and goals. This process is a means of implementing the Grand Strategy System. It provides a framework for an integrated systems perspective and the need for an organizational learning process. A systems perspective is approached here on two levels: (1) the formal and informal methods and procedures (systems) that operate in order to get things done (from purchasing to political accommodation) in an organization (e.g., Waterman, et. al., 1980), and (2) a systems thinking approach to planning, problem solving and decision making which incorporates interrelationships among systems as primary elements of the manager's conceptual representation (mental model) of the organization (e.g., Hicks, 1991). Organizational Teaming can be characterized as a process through which management teams coordinate and modify their mental models of the organization, its goals, its environment, and the information, strategies, systems, and actions required to achieve continuous improvement (e.g., Senge, 1990; De Geus, 1988). The activities of this research area focus on documenting and organizing past strategies to augment systems thinking and organizational learning. DOE

DESIGN, DEVELOPMENT, AND TESTING OF AN AUTOMATED KNOWLEDGE-ACQUISITION TOOL TO AID PROBLEM SOLVING, DECISION MAKING, AND PLANNING Ph.D. Thesis
T. G. Kotnour 14 Sep. 1992 239 p
(Contract DE-FG02-91NP-00119)
(DE93-010239; DOE/NP-00119/T4) Avail: CASI HC A11/MF A03 (US Sales Only)

This research studies the process of acquiring knowledge from experts. Forty subjects used a machine-aided knowledge-acquisition tool to model a word processing task. With this tool, the subjects developed models that were 72.8% accurate with baseline model and 88.5% consistent. Thirty-one knowledge-acquisition methods were evaluated and one chosen and automated in the form of a machine-aided knowledge-acquisition tool (choice is made using 5 criteria including information processing model of problem solving). Performance of this tool is evaluated in terms of accuracy and consistency of the knowledge bases generated. A baseline is derived to which other knowledge-acquisition tools' performance can be compared. Four groups of changes are suggested for the user interface and operation modes. DOE

PATTERN OF FEDERAL PROCUREMENT FROM MINORITY AND WOMEN-OWNED SMALL BUSINESS Final Report
J. Skolnik and H. J. Chmelynski 22 Jul. 1992 121 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract SBA-5645-OA-90)
(PB93-189355; JackFau-92-414) Avail: Issuing Activity (National Technical Information Service (NTIS))

In 1988, 3.0 percent of the $195 billion spent by the federal government in procuring goods and services went to minority-owned firms. Although minority- and women-owned firm procurement seems quite low, this does not necessarily mean that an inequitable situation exists. It has been suggested, for example, that federal government procurement may be concentrated in industries that are dominated by large businesses. By comparing the pattern of federal procurement from minority- and women-owned firms with statistics on the prevalence of minority- and women-owned businesses in the economy as a whole, the study measures that extent to which miniority- and women-owned businesseS receive a proportionate share of federal procurement. The study also identifies the sectors where minority- and women-owned businesses have been successful or unsuccessful in obtaining federal business. NTIS

ASSESSING THE ADEQUACY OF THE INDUSTRIAL BASE Final Report
David P. Garner, Salvatore J. Culosi, William W. Bothwell, Maurice E. Edlund, Michael G. Jackson, James S. Thomason, Peter S. Brooks, Richard Cheslow, Janet Nauta, and John F. Starns et al May 1992 426 p
Prepared in cooperation with Army Logistics Evaluation Agency, Cumberland, PA; Inst. for Defense Analysis, Alexandria, VA; and Analytic Sciences Corp., and Analytic Sciences Corp., Alexandria, VA
(Contract MDA903-90-C-0006)
(AD-A264954) Avail: CASI HC A19/MF A04

In the wake of Operations Desert Shield/Desert Storm and as a means of preparing to meet the challenges confronting it over the next 10 years, the Army chartered the Integrated Army Mobilization Study (IAMS) in Jan. 1991 to identify the major impediments to mobilizing U.S. Forces to meet future contingencies. Facing declining procurement budgets, termination of production runs, and possible loss of critical subtier vendors, the Army was especially concerned with the adequacy of the industrial base to satisfy future warfighting materiel requirements. Accordingly, as part of the total IAMS effort, the Assistant Secretary of the Army for Installations, Logistics, and Environment asked the Deputy Chief of Staff for Logistics to sponsor a study to assess the adequacy of the industrial base to support Operation Desert Storm and similar contingencies in FY-99. As the study evolved, the Army defined its desired taskings more clearly and assigned tasks to separate organizations. In all, four contracts were authorized to address distinct segments of the issue. DTIC

GUIDELINES FOR THE ESTABLISHMENT AND OPERATION OF AN RFP (REQUEST FOR PROPOSAL) LIBRARY Interim Report
Bill Reid and Jean Chisholm 29 Mar. 1993 37 p
(AF Proj. 9993)
(AD-A265894; AD-E201466; PL-TR-93-2090; SR-272; XC-PL/HANSCOM) Avail: CASI HC A03/MF A01

This report describes guidelines for the establishment and operation of a Request for Proposal (RFP) Library. An RFP Library is a set of documents, often ranging in level of classification and limitation, that is viewed by potential government contractors. The report is divided into three sections. The first part contains the information necessary to set up an unlimited, unclassified RFP Library. The second section of the report outlines the security measures that must be taken with limited and classified documents. The final part of the report contains information on how to sign potential contractors into and out of the RFP Library. DTIC

NATIONAL SBIR PHASE 3 COMMERCIALIZATION CONFERENCE Final Report, 10-11 Jun. 1993
Jun. 1993 159 p Conference held in Orlando, FL, 10-11 Jun. 1993
(AD-A266083) Avail: CASI HC A08/MF A02

The Small Business Innovation Research Phase III Conference, 10-11

June 1993, was organized to foster partnerships between the most successful SBIR firms and other small businesses, major corporations, venture capitalists, and technical representatives of Federal organizations. This document, provided to participants, describes the capabilities and goals of over 160 of the companies that were represented at the conference. Participating small companies all have been successful in developing technically innovative products and processes under the Federal SBIR program. Goals of the SBIR program include stimulating technological innovation, strengthening the role of small business in meeting Federal R&D needs, encouraging participation by minority and disadvantaged firms, and increasing the commercial application of Federally-supported research and development results. Conference attendees included: 75 major corporations, 233 small businesses, and 17 venture capitalists. DTIC

FINANCIAL MANAGEMENT: NASA'S FINANCIAL REPORTS ARE BASED ON UNRELIABLE DATA
Oct. 1992 77 p
(AD-A265690; GAO/AFMD-93-3) Avail: CASI HC A05/MF A01

This report presents the results of GAO's review of the National Aeronautics and Space Administration's (NASA) financial management operations. It discusses a number of systems and internal control weaknesses which have resulted in unreliable data for managing and reporting on NASA's operations, as well as the status of related improvement efforts. GAO undertook this review at NASA's four largest Centers and its headquarters offices to evaluate NASA's high-risk areas that are vulnerable to waste, abuse, and mismanagement. The Office of Management and Budget (OMB) has designated NASA's financial management systems to be at risk, and OMB and GAO have designated NASA's contract administration as high risk because of previously identified weakness and NASA's increased reliance on its contractors for data. DTIC

VARIABLE RATE TRANSFER OF OPTICAL INFORMATION Patent Application
Sonlink N. Phuvan, inventor (to Navy) 24 Mar. 1993 18 p
(AD-D015758; US-Patent-Appl-SN-046254) Avail: CASI HC A03/MF A01

In accordance with the present invention, a variable optical delay module is introduced within an optical ring to provide control of the data transfer rate and optical unity gain. Two optically addressed spatial light modulators of the ferroelectric liquid crystal based type, according to one embodiment, are utilized in the optical delay module to avoid corruption of the data within the optical ring. The data is stored in one of the spatial light modulators during data transfer to the other spatial light modulator so that neither modulator would be reading from itself to overwrite and corrupt its data. An image input impinges on one spatial light modulator producing a charge distribution within the spatial modulators which matches the local intensity of the image input. This charge distribution switches the orientation of the ferroelectric liquid if it exceeds a selected threshold charge magnitude. DTIC

This report is concerned with agents that act to gain information. In previous work, we developed agent models combining qualitative modeling with real-time control. That work, however, focused primarily on actions that affect physical states of the environment. The current study extends that work by explicitly considering problems of active information-gathering and by exploring specialized aspects of information-gathering in computational perception, learning, and language. In our theoretical investigations, we analyzed agents into their perceptual and action components and identified these with elements of a state-machine model of control. The mathematical properties of each was developed in isolation and interactions were then studied. We considered the complexity dimension and the uncertainty dimension and related these to intelligent-agent design issues. We also explored active information gathering in visual processing. Working within the active vision paradigm, we developed a concept of 'minimal meaningful measurements' suitable for demand-driven vision. We then developed and tested an architecture for ongoing recognition and interpretation of visual information. In the area of information gathering through learning, we explored techniques for coping with combinatorial complexity. We also explored information gathering through explicit linguistic action by considering the nature of conversational rules, coordination, and situated communication behavior. Author (revised)

A BROWSE FACILITY FOR EARTH SCIENCE REMOTE SENSING DATA: CENTER DIRECTOR'S DISCRETIONARY FUND FINAL REPORT
P. J. Meyer May 1993 16 p
(Proj. 91-09)
(NASA-TM-108413; NAS 1.15:108413) Avail: CASI HC A03/MF A01

An image data visual browse facility is developed for a UNIX platform using the X Windows 11 system. It allows one to visually examine reduced resolution image data to determine which data are applicable for further research. Links with a relational data base manager then allow one to extract not only the full resolution image data, but any other ancillary data related to the case study. Various techniques are examined for compression of the image data in order to reduce data storage requirements and time necessary to transmit the data on the internet. Data used were from the WetNet project. Author (revised)

THE FIRST TEXT RETRIEVAL CONFERENCE (TREC-1)
Donna K. Harman, ed. Mar. 1993 517 p Conference held in Gaithersburg, MD, 4-6 Nov. 1992; sponsored by NIST and DARPA Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-191641; NIST/SP-500/207) Avail: Issuing Activity (National Technical Information Service (NTIS))

The first Text REtrieval Conference (TREC-1) was held in early November 1992 and was attended by about 100 people involved in the 25 participating groups. The goal of the conference was to bring research groups together to discuss their work on a new large test collection. There was a large variation of retrieval techniques reported on, including methods using automatic thesauri, sophisticated term weighting, natural language techniques, relevance feedback, and advanced pattern matching. As results had been run through a common evaluation package, groups were able to compare the effectiveness of different techniques and discuss how differences among the systems affected performance. AUTOMATIC WORD CATEGORIZATION: AN INFORMATION-THEORETIC APPROACH
Marc M. Lankhorst and Rudy Moddemeijer 18 Dec. 1992 18 p
(CS-9209; ETN-93-94347) Copyright Avail: CASI HC A03/MF A01

A novel approach to the automatic categorization of words from raw data is presented. Occurrences of word pairs in text are counted. A hierarchical clustering technique on this frequency data is used to obtain a classification of words into linguistic categories. As a distance criterion in the clustering process, the loss of mutual information caused by combining two clusters into a single new cluster is used. The main advantage of such a method is the ability to construct linguistic categories that combine both syntactic and semantic/pragmatic factors. Results of the application of this method on letter data and on a word corpus are shown. Words are not only classified on the basis of their syntactic categories, but also with respect to aspects that are related to their meanings. The method can form the basis of a system that uses a much finer categorization of words than is feasible using traditional grammar based approaches. Plans to use it in a layered system of artificial neural networks that are trained to recognize higher level constituents are considered. ESA

The major Superconducting SuperCollider (SSC) experiments are expected to produce up to 1 Petabyte of data per year each. Once the primary reconstruction is completed by farms of inexpensive processors, I/O becomes a major factor in further analysis of the data. We believe that the application of database techniques can significantly reduce the I/O performed in these analyses. We present examples of such I/O reductions in a prototype based on relational and object-oriented databases of Collider Detector and Fermilab (CDF) data samples. DOE

AN ALTERNATIVE TO SNEAKERNET
S. Orrell and S. Ralstin 1993 14 p Presented at the 15th Computer Security Group Training Conference: Mission Possible-Connected and Protected, Albuquerque, NM, 3-6 May 1993
(Contract DE-AC08-88NV-10617)
(DE93-012130; EGG-10617-6097; CONF-9305151-1) Avail: CASI HC A03/MF A01

Security plans for classified computer systems often specify that only a small percentage of the data processed will be classified. Thus, the bulk of the data on such secure systems is unclassified. This situation requires that some mechanism be provided for moving files to or from the open environment. For many years, this has been accomplished by writing selected files to a magnetic medium, and carrying it to another system where the files are retrieved. These procedures, in many cases, have been developed informally and ad hoc to a specific transfer requirement. This media transport process, referred to as sneakernet, often is manually logged, if at all, and controlled only by administrative procedures. While sneakernets may isolate secure systems from direct attack, other security concerns remain. There has been little guidance available for handling such transfers in a secure manner. Comprehensive criteria for the security evaluation of the procedures used for these transfers have yet to be published. This paper examines the security concerns associated with transfers of unclassified files between security environments and develops a set of criteria which can be used in evaluating the security of any system or procedure for that purpose. Methods for bidirectional unclassified file transfer between secure and open environments could range from completely manual to fully automated. The criteria developed, however, are intended to be generic and to apply to any system for the purpose, existing or proposed. DOE

FLIGHT DYNAMICS DIRECTORATE (FDD) HISTORICALLY BLACK COLLEGES AND UNIVERSITIES (HBCU'S) DATABASE MANAGMENT SYSTEM: A USER'S GUIDE Final Report, May 1991 - Sep. 1992
James R. Johnson Nov. 1992 18 p
(Contract F33615-90-C-3211)
(AD-A264947; ASIAC-TR-92-10; WL-TR-92-3109) Avail: CASI HC A03/MF A01

Structural Research Capability Database of HBCU's was developed which can be used to recall data about HBCU faculty capabilities and research interests, and university research facilities. The records are focused toward Flight Dynamics Directorate research and technology needs and should facilitate and increase faculty and student participation in the Flight Dynamics Directorate research programs by familiarizing Flight Dynamics Directorate in-house researchers with those at the cited HBCU's. Additional records may be appended to the database. More data were obtained than was contemplated, some universities provided brochures and other additional published data. This report serves as a user's guide for the database program. DTIC

NASA/DOD AEROSPACE KNOWLEDGE DIFFUSION RESEARCH PROJECT. REPORT 17: A COMPARISON OF THE TECHNICAL COMMUNICATION PRACTICES OF DUTCH AND US AEROSPACE ENGINEERS AND SCIENTISTS
Rebecca O. Barclay (Rensselaer Polytechnic Inst., Troy, NY.), Thomas E. Pinelli, and John M. Kennedy (Indiana Univ., Bloomington.) Washington Jul. 1993 70 p
(RTOP 505-90-00)
(NASA-TM-108987; NAS 1.15:108987) Avail: CASI HC A04/MF A01

As part of Phase 4 of the NASA/DoD Aerospace Knowledge Diffusion Research Project, two studies were conducted that investigated the technical communications practices of Dutch and U.S. aerospace engineers and scientists. Both studies have the same seven objectives: first, to solicit the opinions of aerospace engineers and scientists regarding the importance of technical communications to their profession; second, to determine the use and production of technical communications by aerospace engineers and scientists; third, to seek their views about the appropriate content of an undergraduate course in technical communications; fourth, to determine aerospace engineers' and scientists' use of libraries, technical information centers, and on-line data bases; fifth, to determine the use and importance of computer and information technology to them; sixth, to determine their use of electronic networks; and seventh, to determine their use of foreign and domestically produced technical reports. A self-administered questionnaire was distributed to aerospace engineers and scientists at the National Aerospace Laboratory (NLR), and NASA Ames Research Center, and the NASA Langley Research Center. The completion rates for the Dutch and U.S. surveys were 55 and 61 percent, respectively. Responses of the Dutch and U.S. participants to selected questions are presented. Author (revised)

DESIGN ISSUES FOR HIGH PERFORMANCE ENGINEERING INFORMATION SYSTEMS Final Report, 1 Mar. 1989 - 30 Apr. 1992
Nick Roussopoulos, Timos Sellis, Leo Mark, and Christos Faloutsos 20 Apr. 1992 21 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0303-89)
(AD-A264839; AFOSR-93-0210TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

It is increasingly being recognized that an Engineering Information System will be the fundamental component of any design and manufacturing system in the future and that all components in such a system have to be engineered around the management and control of information. Commercially available database systems do not meet the information and processing needs of design and manufacturing environments. Consequently, extensions to database systems are necessary to realize Engineering Information Systems. These systems will support multimedia databases of significant size and complexity, and, therefore, one of the most important issues is performance. The computational and architectural aspects of EIS and rule management techniques for maintaining consistency were addressed in this project. The studies produced promising models and solutions. INFORMATION RESOURCES MANAGEMENT LONG-RANGE PLAN, FY1994
Apr. 1993 145 p
(DE93-013898; DOE/AD-0043) Avail: CASI HC A07/MF A02

This document describes IRM activities and the information technology resources and capabilities of the Department, the future requirements, and the strategies and plans to satisfy the identified requirements. The long-range planning process provides the systematic means to meet this objective and assists the Department in assuring that information technology (IT) support is provided in an efficient, effective, and timely manner so that its programmatic missions can be accomplished. Another important objective of the Plan is to promote better understanding, both within and external to the Department, of its IT environment, requirements, issues, and recommended solutions. This DOE IRM Plan takes into consideration the IRM requirements of approximately 50 different sites. The annual long-range planning cycle for supporting this Plan was initiated by a Call in August 1991 for site plans to be submitted in February 1992 by those Departmental components and contractors with major IRM requirements. DIRECTORY OF IAEA DATABASES
Dec. 1992 126 p
(DE93-622837; INIS-mf-13507) Avail: CASI HC A07/MF A02 (US Sales Only)

This second edition of the Directory of IAEA Databases has been prepared within the Division of Scientific and Technical Information (NESI). Its main objective is to describe the computerized information sources available to staff members. This directory contains all databases produced at the IAEA, including databases stored on the mainframe, LAN's and PC's. All IAEA Division Directors have been requested to register the existence of their databases with NESI. For the second edition database owners were requested to review the existing entries for their databases and answer four additional questions. The four additional questions concerned the type of database (e.g. Bibliographic, Text, Statistical etc.), the category of database (e.g. Administrative, Nuclear Data etc.), the available documentation and the type of media used for distribution. In the individual entries on the following pages the answers to the first two questions (type and category) is always listed, but the answers to the second two questions (documentation and media) is only listed when information has been made available. THE RELATIONAL-TO-OBJECT-ORIENTED CROSS-MODEL ACCESSING CAPABILITY IN A MULTI-MODEL AND MULTI-LINGUAL DATABASE SYSTEM M.S. Thesis
Richard K. Johnston Mar. 1993 89 p
(AD-A264911) Avail: CASI HC A05/MF A01

Conventional database management systems (DBMS) are stand-alone, each supporting a single data model and corresponding data language (ML). One organization might operate several stand-alone DBMS's independently, each of which requires the knowledge of a different ML to operate. The multi-model and multi-lingual database system offers a different approach. This system supports multiple ML's in a single database system. Thus, a relational database user of the multi-model and multi-lingual database system can create and manipulate a database according to the relational model and the SQL data language. On the same system, a hierarchical user can create and manipulate a database according to the hierarchical model and DL/I data language. Besides supporting many different models and languages on a single system, the multi-model and multi-lingual database system also allows the user to access a database created according to one ML as if it were created according to another. Thus, a relational user could manipulate a hierarchical database as if it is relational, i.e., the user would use a relational schema and SQL commands to manipulate a hierarchical database. The Cross-model accessing capability, Database design, Database implementation, Database management systems, base-model, and base-language (i.e., hierarchical and DL/1) are invisible to the user. This additional capability is termed the cross-model accessing capability. At this time the multi-model and multi-lingual database system supports the following ML's: relational and SQL, hierarchical and DL/I, network and CODASYL-DML, and object-oriented and the object-oriented data language. The system also supports a relational-to-hierarchical cross-model accessing capability. DTIC

INFORMATION RESOURCES MANAGEMENT PLAN OF THE FEDERAL GOVERNMENT
Nov. 1992 298 p Prepared in cooperation with General Services Administration, Washington, DC, and Commerce Dept., Washington, DC
(ISBN-0-16-037895-8) Avail: CASI HC A13/MF A03; SOD HC

Bulletin 92-05, 'Information Resources Management (IRM) Plans', issued 6 Mar. 1992, encourages Federal agencies to establish an integrated approach to information resources management. Moreover, the Bulletin required agencies to describe their commitments and accomplishments toward establishing a comprehensive strategy for managing agency information resources throughout the 'information life cycle,' including information creation, collection, processing, dissemination and management. The purposes of this publication are the following: to reflect Federal agencies' focus on program priorities by identifying how plans for major information collections and information technology will support those priorities; to provide an accounting of actual reductions in the burden of Federal information collection and recordkeeping accomplished by Federal agencies during Fiscal Year (FY) 1991 and of the reductions planned by these agencies for FY 1992 and FY 1993; to promote program-based planning for the use of information resources that will make Government service delivery more effective, efficient, and responsive; to support the activities of Congress and other oversight agencies; to provide information to Federal agencies on trends and directions in information resources management; and to inform the public of the current state of Federal IRM activities so that they can more meaningfully participate in those activities. MACHINE TRANSLATION TECHNOLOGY: A POTENTIAL KEY TO THE INFORMATION AGE
Jan. 1993 59 p See also AD-225965 and PB92-861731
(PB93-134336) Avail: CASI HC A04/MF A01

Today nearly half of the world's scientific and technological literature is written in languages other than English. Currently, machine translation (MT) can produce comprehensible translated text in a few languages, but human editing is often required to produce a truly polished translation. The United States is strong in basic research on natural language processing, and leads the world in the diversity of language pairs under development. The challenge is in converting its formidable research potential and know-how into commercial operating systems. The single most challenging competitor-nation in MT is Japan. Japan is ahead of the United States in development of MT systems--in terms of the number of systems, variety of applications, and development of knowledge sources--but not in basic research. Japan also leads the U.S. in commercial use and general acceptance of MT, and in integration of MT into the office environment. Author

DEFENSE: HEALTH CARE
3 Jun. 1993 8 p Sponsored by DOD
(AD-A265914; GAO/IMTEC-93-29R) Avail: CASI HC A02/MF A01

In Oct. 1989 the Department of Defense introduced its Corporate Information Management (CIM) initiative to reengineer its business practices and make better use of information technology. In May 1990, a Medical Functional Group was established within the Office of the Assistant Secretary of Defense for Health Affairs to institutionalize the CIM process within the Military Health Services System. This letter addresses our review of CIN's implementation in military health services--one of the eight functional areas selected for initial CIM implementation. At a time when health care costs are rising dramatically, CIM offers opportunities to reduce not only health care information technology expenses but, more important, the overall costs of providing care. ANALYSIS OF THE ARMY'S INSTALLATION SUPPORT MODULES WITH THE PRIVATE SECTOR'S OPEN INFORMATION SYSTEMS Final Report
Paul G. Andrews 9 Apr. 1993 76 p
(AD-A265667) Avail: CASI HC A05/MF A01

Installation management within the U.S. Army is comprised of a myriad of basic management functions such as real property acquisition and personnel accountability. These functions are performed by installation organizations which are responsible for managing the manpower, funds, and equipment assigned to the installation during peace and wartime conditions. Each installation organization uses an information system tailored to its specific mission to perform daily tasks. However, this network configuration is characterized by the lack of data sharing capability, and it does not promote qualitative management of military resources. In order to incorporate data sharing among the installation organizations and enhance installation management, the Army has developed a new information system called Installation Support Modules (ISM). The ISM is a computer hardware, software, and communications-infrastructure designed to provide installation organizations with the capability of horizontal and vertical data sharing. The Army's acquisition strategy for the ISM is to develop the system with the latest computer and information technology, Open Systems Environment (OSE). DTIC

NATIONAL PATTERNS OF R AND D RESOURCES, 1992
John E. Jankowski, Jr. Oct. 1992 85 p
(NSF-92-330) Avail: CASI HC A05/MF A01

The National Science Foundation (NSF) sponsors a series of surveys to collect information on the financial and human resources devoted to research and development (R&D). In this report, such NSF survey data on the various sectors of the U.S. economy - industry, government, academia and selected nonprofit organizations - are aggregated so that the components of the overall R&D effort are placed in a national context. Information presented in National Patterns includes: the level of R&D expenditures; the sources of such funds; the sector or organization performing the R&D; the character of work undertaken (i.e., whether it is basic research, applied research, or development); the number of scientists and engineers employed in R&D; and international comparisons with the U.S. effort. The national totals reported here incorporate data available from the several Division of Science Resources Studies (SRS) surveys as of May 14, 1992. These notes provide a brief introduction to the concepts used in the report. Important changes and revisions from previous National Patterns reports also are highlighted. Complete definitions, descriptions of projection methodologies, and references to the underlying survey reports are included in an appendix. Derived from text

N94-11351# Executive Office of the President, Washington, DC. National Performance Review.
FROM RED TAPE TO RESULTS: CREATING A GOVERNMENT THAT WORKS BETTER AND COSTS LESS
Albert Gore, Jr. et al 7 Sep. 1993 170 p Revised Original contains color illustrations
Avail: CASI HC A08/MF A02; SOD HC

This report represents the beginning of what will be--what must be--an ongoing commitment to change. It includes actions that will be taken now, by directive of the President; actions that will be taken by the cabinet secretaries and agency heads; and recommendations for congressional action. The National Performance Review focused primarily on how government should work, not on what it should do. Our job was to improve performance in areas where policymakers had already decided government should play a role. We examined every cabinet department and 10 agencies. Derived from text

N94-11353# Executive Office of the President, Washington, DC. National Performance Review.
FROM RED TAPE TO RESULTS: CREATING A GOVERNMENT THAT WORKS BETTER AND COSTS LESS. EXECUTIVE SUMMARY
Albert Gore, Jr. et al 7 Sep. 1993 24 p Original contains color illustrations
Avail: CASI HC A03/MF A01; SOD HC

The National Performance Review is about change--historic change--in the way the government works. It's time we had a new customer service contract with the American people, a new guarantee of effective, efficient, and responsive government that puts our customers first and demonstrates to the American people that their tax dollars will be treated with respect for the hard work that earned them. The National Performance Review is about moving from red tape to results to create a government that works better and costs less. This is a summary of the first product of our efforts. In it, we make hundreds of recommendations saving $108 billion over five years. Derived from text

The report documents the procedures, events, and results of vehicle dynamic tests carried out on the ASEA-Brown Boveri (ABB) X2000 tilt body trainset in the U.S. between Oct. 1992 and Jan. 1993. These tests, sponsored by Amtrak and supported by the FRA, were conducted to assess the suitability of the X2000 trainset for safe operation at elevated cant deficiencies and speeds in Amtrak's Northeast Corridor under existing track conditions in a revenue service demonstration. The report describes the safety criteria against which the performance of the X2000 test train was examined, the instrumentation used, the test locations, and the track conditions. Preliminary results are presented from tests conducted on Amtrak lines between Philadelphia and Harrisburg, PA, and between Washington DC and New York NY, in which cant deficiencies of 12.5 inches and speeds of 154 mph were reached in a safe and controlled manner. The significance of the results is discussed, and preliminary conclusions and recommendations are presented. NTIS

TECHNICAL UPDATE: JOHNSON SPACE CENTER SYSTEM USING A SOLID ELECTROLYTIC CELL IN A REMOTE LOCATION TO MEASURE OXYGEN FUGACITIES IN CO/CO2 CONTROLLED-ATMOSPHERE FURNACES Interim Report
A. J. G. Jurewicz (Lockheed Engineering and Sciences Co., Houston, TX.), R. J. Williams, L. Le (Lockheed Engineering and Sciences Co., Houston, TX.), J. Wagstaff (Lockheed Engineering and Sciences Co., Houston, TX.), G. Lofgren, A. Lanier (Lockheed Engineering and Sciences Co., Houston, TX.), W. Carter (Lockheed Engineering and Sciences Co., Houston, TX.), and A. Roshko (National Inst. of Standards and Technology, Boulder, CO.) Sep. 1993 39 p
(Contract NAS9-11410)
(NASA-TM-104774; S-727; NAS 1.15:104774) Avail: CASI HC A03/MF A01

Details are given for the design and application of a (one atmosphere) redox-control system. This system differs from that given in NASA Technical Memorandum 58234 in that it uses a single solid-electrolytic cell in a remote location to measure the oxygen fugacities of multiple CO/CO2 controlled-atmosphere furnaces. This remote measurement extends the range of sample-furnace conditions that can be measured using a solid-electrolytic cell, and cuts costs by extending the life of the sensors and by minimizing the number of sensors in use. The system consists of a reference furnace and an exhaust-gas manifold. The reference furnace is designed according to the redox control system of NASA Technical Memorandum 58234, and any number of CO/CO2 controlled-atmosphere furnaces can be attached to the exhaust-gas manifold. Using the manifold, the exhaust gas from individual CO/CO2 controlled atmosphere furnaces can be diverted through the reference furnace, where a solid-electrolyte cell is used to read the ambient oxygen fugacity. The oxygen fugacity measured in the reference furnace can then be used to calculate the oxygen fugacity in the individual CO/CO2 controlled-atmosphere furnace. A BASIC computer program was developed to expedite this calculation. Author (revised)

GAS-GRAIN SIMULATION FACILITY (GGSF). VOLUME 2: CONCEPTUAL DESIGN DEFINITION
James M. Zamel Aug. 1993 99 p
(Contract NAS2-13408)
(NASA-CR-177613; A-93101-Vol-2; NAS 1.26:177613) Avail: CASI HC A05/MF A02

This document is Volume 2 of the Final Report for the Phase A Study of the Gas-Grain Simulation Facility (GGSF), and presents the GGSF Conceptual Design. It is a follow-on to the Volume 1 Facility Definition Study, NASA report CR 177606. The development of a conceptual design for a Space Station Freedom (SSF) facility that will be used for investigating particle interactions in varying environments, including various gas mixtures, pressures, and temperatures is delineated. It's not possible to study these experiments on earth due to the long reaction times associated with this type of phenomena, hence the need for extended periods of microgravity. The particle types will vary in composition (solids and liquids), sizes (from submicrons to centimeters), and concentrations (from single particles to 10(exp 10) per cubic centimeter). The results of the experiments pursued in the GGSF will benefit a variety of scientific inquiries. These investigations span such diverse topics as the formation of planets and planetary rings, cloud and haze processes in planetary atmospheres, the composition and structure of astrophysical objects, and the viability of airborne microbes (e.g., in a manned spacecraft). DETECTION OF DUST IMPACTS BY THE VOYAGER PLANETARY RADIO ASTRONOMY EXPERIMENT Final Report, 14 May 1991 - 20 Apr. 1993
David R. Evans 13 Jul. 1993 59 p
(Contract NASw-4617)
(NASA-CR-193281; NAS 1.26:193281) Avail: CASI HC A04/MF A01

The Planetary Radio Astronomy (PRA) instrument detected large numbers of dust particles during the Voyager 2 encounter with Neptune. The signatures of these impacts are analyzed in some detail. The major conclusions are described. PRA detects impacts from all over the spacecraft body, not just the PRA antennas. The signatures of individual impacts last substantially longer than was expected from complementary Plasma Wave Subsystem (PWS) data acquired by another Voyager experiment. The signatures of individual impacts demonstrate very rapid fluctuations in signal strength, so fast that the data are limited by the speed of response of the instrument. The PRA detects events at a rate consistently lower than does the Plasma Wave subsystem. Even so, the impact rate is so great near the inbound crossing of the ring plane that no reliable estimate of impact rate can be made for this period. The data are consistent with the presence of electrons accelerated by ions within an expanding plasma cloud from the point of impact. An ancillary conclusion is that the anomalous appearance of data acquired at 900 kHz appears to be due to an error in processing the PRA data prior to their delivery rather than due to overload of the PRA instrument. DETECTION OF ACCRETING CIRCUMSTELLAR GAS AROUND WEAK EMISSION-LINE HERBIG Ae/Be STARS
C. A. Grady (Applied Research Corp., Landover, MD.), M. R. Perez, and P. S. The (Amsterdam Univ., Netherlands.) 1993 5 p
(NASA-TM-108256; NAS 1.15:108256) Avail: CASI HC A01/MF A01

Archival and recent International Ultraviolet Explorer (IUE) high dispersion spectra of late B stars which reveal the presence of accreting gas with velocities as high as 350 km/s, collisional ionization of the accreting gas to temperatures above the stellar T(sub eff), and column densities intermediate between those observed toward classical Herbig Ae/Be stars and the nearby proto-planetary system beta Pictoris are presented. One of the stars HD 176386, while lacking obvious optical signatures of youth, is a member of the R CrA star formation region, and with an inferred age of 2.8 Myr has not yet arrived on the zero-age main sequence (ZAMS). The other object, an isolated, field B star with pronounced IR excess due to warm, circumstellar dust, 51 Oph, exhibits only modest H(alpha) emission. The combination of high velocity, accreting gas in systems with IR excesses due to circumstellar dust suggests that not only are these objects candidate proto-planetary systems, but that they may represent an extension to higher stellar masses of the weak-emission pre-main sequence (PMS) stars.

LUNAR-ULTRAVIOLET TELESCOPE EXPERIMENT (LUTE) INTEGRATED PROGRAM PLAN Final Report
Janice F. Smith, comp. and Larry Forrest (Cockerham, John M. and Associates, Inc., Huntsville, AL.) 13 Jul. 1993 20 p
(NASA Order H-20750-D)
(NASA-CR-193267; NAS 1.26:193267; Rept-5307-00-9307-F) Avail: CASI HC A03/MF A01

A detailed Lunar Ultraviolet Telescope Experiment (LUTE) program plan representing major decisions and tasks leading to those decisions for program execution are presented. The purpose of this task was to develop an integrated plan of project activities for the LUTE project, and to display the plan as an integrated network that shows the project activities, all critical interfaces, and schedules. The integrated network will provide the project manager with a frame work for strategic planning and risk management throughout the life of the project. Author (revised)

THE ABUNDANCES OF THE ELEMENTS IN SHARP-LINED EARLY TYPE STARS Final Report, 1 May - 31 Jul. 1992
Saul J. Adelman 3 Aug. 1992 8 p
(Grant NAG5-1402)
(NASA-CR-194055; NAS 1.26:194055) Avail: CASI HC A02/MF A01

An International Ultraviolet Explorer (IUE) observing strategy that has yielded co-added spectra with enhanced S/N ratios for several A and B stars was established. New observations by Roby and Adelman using the same technique were added two new Hg-Mn stars into this sample. A long-term study of elemental abundances in this uniform, high-quality set of IUE spectra for 13 stars was begun. The first stages of this project are reported: abundances for N, Cr, Mn, Fe, Co, and Ni. The study of the Fe-peak elements show that our data set can provide accurate abundances and that abundances obtained from UV and optical spectra often are in good agreement. The groundwork for selfconsistent abundance analyses of more exotic elements in our long term project was provided.

PLANETARY ASTRONOMY OF MARS. MARS DATA REDUCTION Final Technical Report, 1 Oct. 1988 - 30 Sep. 1990
Robert B. Singer 30 Sep. 1990 8 p
(Grants NAGw-1408; NAGw-1913)
(NASA-CR-193515; NAS 1.26:193515) Avail: CASI HC A02/MF A01

Grant #NAGW-1408 was specifically awarded to obtain telescopic visible and near-IR spectral imaging of Mars during the 1988 apparition (9/28/88). The observing program was highly successful producing approximately 2 Gbytes of data, but was only funded for one year and virtually all of the funds were spent in data acquisition. The follow-up grant was funded the following year for reduction of these data into a scientifically productive form, which because of the size and nature of our observations, was a non-trivial task. A more detailed scientific analysis of these data (fully reduced) is in progress now and will take a number of years. Extended geologic analyses of the astronomical data are being funded by the NASA Planetary Geology and Geophysics program. The objective was to produce detailed reflectance spectra for contiguous, spatially resolved surface elements covering most of the planet (about +50 degrees to -90 degrees latitude, all longitudes). A total of 6 observing runs, of 3-4 days duration each, were conducted on the University of Arizona's 1.5m telescope on Mt. Bigelow. We present a sketch map showing the approximate total extent of our spectral image coverage. Nearly all of Mars south of 40 degrees N was observed at least once. About half of the area shown was observed multiple times. South of 65 degrees S, including the south polar cap, our coverage is heavily redundant. The first run was conducted June 29 - July 1, 1988 (all dates are UT) to serve as a baseline prior to possible dust storm activity on Mars. The other observing runs were closer to opposition: Sept. 3-6, 13-15, 24-26, and Oct. 5-7 and 16-18. The September and October observations were scheduled to provide maximum longitudinal coverage. This was also intended to provide a balance between surface observations and observations of predicted dust storm activity. No global dust storm developed in 1988, so we have a large volume of data for the surface of Mars. Derived from text

ACCELERATION OF POSITRONS IN SUPERNOVA SHOCKS Final Technical Report, 15 Apr. 1989 - 15 Apr. 1992
Donald C. Ellison 15 Apr. 1992 4 p
(Grant NAG5-1131)
(NASA-CR-193713; NAS 1.26:193713) Avail: CASI HC A01/MF A01

During this project we investigated the acceleration of leptons (electrons and positrons) in collisionless shock waves. In particular, we were interested in how leptons are accelerated in the blast waves existing in the remnants of supernova explosions. Supernova remnants (SNRs) have long been considered as the most likely source of galactic cosmic rays but no definite connection between SNRs and the cosmic rays seen at earth can be made. Only by understanding lepton acceleration in shocks can the rich SNR data base be properly used to understand cosmic ray origins. Our project was directed at the neglected aspects of lepton acceleration. We showed that the efficiency of lepton acceleration depended critically on the lepton injection energy. We showed that, even when infection effects are not important, that proton and lepton distribution functions produced by shocks are quite different in the critical energy range for producing the observed synchrotron emission. We also showed that transrelativistic effects produced proton spectra that were not in agreement with standard results from radio observations, but that the lepton spectra were, in fact, consistent with observations. We performed simulations of relativistic shocks (shocks where the flow speed is a sizable fraction of the speed of light) and discovered some interesting effects. We first demonstrated the power of the Monte Carlo technique by determining the shock jump conditions in relativistic shocks. We then proceeded to determine how relativistic shocks accelerate particles. We found that nonlinear relativistic shocks treat protons and leptons even more differently than nonrelativistic shocks. The transrelativistic effects on the shock structure from the heavy ion component reduces the lepton acceleration to a tiny fraction of the ion acceleration. This effect is dramatic even if high energy leptons (many times thermal energy) are injected, and was totally unexpected. Our results have important consequences for astrophysical environments expected to harbor relativistic flows such as extra-galactic radio sources and accretion onto compact objects. ADVANCED STATISTICAL METHODS FOR IMPROVED DATA ANALYSIS OF NASA ASTROPHYSICS MISSIONS Final Technical Report, 1 Feb. 1990 - 31 Jan. 1992
Eric D. Feigelson 1992 14 p
(Grant NAGw-1917)
(NASA-CR-193514; NAS 1.26:193514) Avail: CASI HC A03/MF A01

The investigators under this grant studied ways to improve the statistical analysis of astronomical data. They looked at existing techniques, the development of new techniques, and the production and distribution of specialized software to the astronomical community. Abstracts of nine papers that were produced are included, as well as brief descriptions of four software packages. The articles that are abstracted discuss analytical and Monte Carlo comparisons of six different linear least squares fits, a (second) paper on linear regression in astronomy, two reviews of public domain software for the astronomer, subsample and half-sample methods for estimating sampling distributions, a nonparametric estimation of survival functions under dependent competing risks, censoring in astronomical data due to nondetections, an astronomy survival analysis computer package called ASURV, and improving the statistical methodology of astronomical data analysis. THE THREE-POINT FUNCTION AS A PROBE OF MODELS FOR LARGE-SCALE STRUCTURE
Joshua A. Frieman and Enrique Gaztanaga (Oxford Univ., England.) 19 Jun. 1993 28 p
(Grant NAGw-2381)
(NASA-CR-193249; NAS 1.26:193249; FERMILAB-Pub-93/140-A) Avail: CASI HC A03/MF A01

The consequences of models of structure formation for higher-order (n-point) galaxy correlation functions in the mildly non-linear regime are analyzed. Several variations of the standard Omega = 1 cold dark matter model with scale-invariant primordial perturbations were recently introduced to obtain more power on large scales, R(sub p) is approximately 20 h(sup -1) Mpc, e.g., low-matter-density (non-zero cosmological constant) models, 'tilted' primordial spectra, and scenarios with a mixture of cold and hot dark matter. They also include models with an effective scale-dependent bias, such as the cooperative galaxy formation scenario of Bower, etal. It is shown that higher-order (n-point) galaxy correlation functions can provide a useful test of such models and can discriminate between models with true large-scale power in the density field and those where the galaxy power arises from scale-dependent bias: a bias with rapid scale-dependence leads to a dramatic decrease of the hierarchical amplitudes Q(sub J) at large scales, r is approximately greater than R(sub p). Current observational constraints on the three-point amplitudes Q(sub 3) and S(sub 3) can place limits on the bias parameter(s) and appear to disfavor, but not yet rule out, the hypothesis that scale-dependent bias is responsible for the extra power observed on large scales. THE CONTROLLING PARAMETERS OF THE INTEGRATED FLUX OF A STELLAR POPULATION Ph.D. Thesis
Guy Worthey 1992 325 p
Avail: Univ. Microfilms Order No. DA9312446

Stellar evolutionary isochrones are coupled with mostly theoretical flux distributions of stars in order to predict the flux distributions and colors of stellar populations as a function of population age and metallicity. Twenty one empirical indices of absorption feature strengths are measured for ensembles of stars of differing ages, temperatures, and metallicities. These indices are expressed as polynomials in stellar temperature, surface gravity, and metallicity, and are applied to the population models to predict index strengths as a function of population age and metallicity. Checks are made against stellar observations. The model predictions are compared to measured indices of elliptical galaxies. The logarithmic ratio (Mg/Fe) (which is zero for a scaled solar ratio) is shown to be greater than that of the most metal-rich stars in the solar neighborhood in giant elliptical galaxies. Since (Mg/Fe) is probably near zero for metal-rich stars, (Mg/Fe) appears to be greater than zero in giant ellipticals, but not in smaller, M32-class, ellipticals. This behavior is probably mirrored in Na and CN indices, suggesting that all light elements are relatively enhanced in giant ellipticals, on average. The nucleosynthetic history of giant ellipticals must differ from that of smaller ellipticals. Surface brightness fluctuation magnitudes are predicted. Models agree with the empirical I-band calibration, giving extragalactic distances which may be good to 10 percent for galaxies well-measured in two passbands. Qualitative agreement is also reached in fluctuation color-color diagrams and color-index diagrams. A fluctuation magnitude which is independent of color probably exists between Cousins I and Johnson J. The model results are tabulated. The sensitivity of all model predictions with age and metallicity are explored. H(Beta) and the G band provide the best age sensitivity of any color or index yet studied; Fe features are the most metallicity sensitive in the absence of abundance ratio differences. A factor of three change in age produces the same change in most colors and indices as a factor of two in Z. The effects of Z, age, and abundance ratio differences most profoundly affect the integrated light of stellar population. Other parameters have effects comparable to the model uncertainties. Dissert. Abstr.

N94-11582 Northwestern Univ., Evanston, IL.
THE EXCITATION OF CYANOGEN AND IONIZED CARBON IN INTERSTELLAR AND EXTRAGALACTIC GAS CLOUDS Ph.D. Thesis
Katherine Carol Roth 1992 223 p
Avail: Univ. Microfilms Order No. DA9309445

The goal of this dissertation is to precisely determine the temperature of the cosmic microwave background (CMB) and explore the behavior of this radiation in the past through observations of interstellar CN and C II in QSO absorption-line systems. We have measured the CN excitation in the diffuse clouds toward zeta Ophiuchi, zeta Persei, HD 27778, HD 21483 and HD 154368. We find J = 0 to 1 rotational excitation temperatures of T(sub ex) = 2.737 +/- 0.025, 2.774(+0.086, -0.091), 2.769(+0.093, -0.099), 2.771(+0.057, -0.060) and 2.68(+0.22, -0.33) K respectively. The fact that these values are all consistent with each other strongly suggests that local processes contribute little to the CN rotational excitation. After small corrections for these effects, we find a weighted average temperature of T(sub CMB) = 2.733(+0.023, -0.031) K for the CMB at 2.64 mm. This value agrees very well with the preliminary COBE temperature of T(sub CMB) = 2.735 +/- 0.06 K found from direct measurements of the short-wavelength CMB spectrum. The agreement in these two measurements resulting from completely different methods attests to the accuracy of each approach and reaffirms the global nature of the CMB radiation. We have obtained spectra of the C II lines in several damped Lyman alpha QSO absorbers in an effort to measure the temperature of the CMB in the past. The implied fine-structure population ratio toward the QSO 0347-383 (z(sub em) = 3.228) yields an upper limit of T(sub CMB) less than or = 14K at a red shift Z(sub abs) = 3.024. Since the observed excitation is most likely dominated by local collisional processes, we find respective upper limits on the electron and hydrogen atom densities of 0.02 and 10 cm(exp -3) in this system. The weak Zn II lines serve as an indicator of the system metallicity, which we have determined to be approximately = 10 percent solar for this absorber. In addition, the measured dust depletions determined from Cr II and Ni II absorption imply that both the 0347-383 and O551-366 (Z(sub abs) = 1.961) systems have dust-to-gas ratio about 10 percent of the Milky Way disk value. These results are consistent with previous work by Meyer and Roth (1990b) on damped Lyman-alpha absorbers at a red shift of Z(sub abs) is approximately = 2. Author

THE IR PROPERTIES OF RINGED GALAXIES AND THE IRAS DATABASE Final Technical Report, 1 Jul. 1991 - 30 Jun. 1993
Ronald J. Buta and Deborah A. Crocker Jun. 1993 4 p
(Grant NAG5-1643)
(NASA-CR-194286; NAS 1.26:194286) Avail: CASI HC A01/MF A01

Our study of the Infrared Astronomy Satellite (IRAS) properties of ringed galaxies has been largely successful. We have identified what we think is the probable cause of the differences in the IRAS properties among non-interacting barred galaxies as the pattern speed of the bar. The key to identifying this parameter has been our focusing the study on outer-ringed galaxies where we know precisely what is present in the central regions (from available BVI CCD images in our library of images). The theory is that outer rings, through their morphology and other characteristics, can be identified with the outer Lindblad resonance, one of the major resonances in galaxy structure. Using a library of n-body simulations for comparison, we can reliably infer both low and high pattern speed galaxies from the appearance of outer rings and the existence of other ring features. It is clear that in some barred galaxies, the bar pattern speed is high enough to avoid an inner Lindblad resonance, hence such objects do not contain nuclear or circumnuclear star formation. The IRAS observations are most sensitive to nuclear star formation in early-type barred galaxies, and will thus select those barred galaxies where the pattern speed is low enough to allow an inner Lindblad resonance to exist. High pattern speed barred galaxies therefore weaken the correlation between bars and infrared excess. This finding helps to reconcile the inconsistent results found between different studies on the correlation between bars and far-IR emission. Derived from text

ON THE DEPLETION IN THE OUTER ASTEROID BELT AND THE STRUCTURE OF THE 4 TO 3 MEAN MOTION RESONANCE Ph.D. Thesis
Judit Gyoergyey Ries 1992 133 p
Avail: Univ. Microfilms Order No. DA9309264

The orbits of about 3000 fictitious asteroids, representing a possible distribution of bodies in the early Solar System, were investigated by numerical integration spanning approximately 38000 years in an effort to reproduce the observed distribution of outer belt asteroids. The equations of the elliptic restricted three body problem were regularized in order to handle close encounters with Jupiter. The estimate of the largest Lyapunov characteristic number and the slope of these estimates were calculated, and their usefulness as indicators of escape orbits was tested. The semimajor axis distribution for orbits that were bounded after 38000 years showed an excess of bodies compared to the observed distribution. The excess is associated with mean motion resonances and high eccentricity orbits. The structure of the 4:3 resonance was investigated by the same method with finer spatial resolution and longer integration time. Based on the estimate of the largest Lyapunov characteristic exponent, the resonance seems to be mostly chaotic. However, longer integration of individual orbits indicated that large Lyapunov characteristic numbers are not reliable predictors of unbounded motion in the elliptic restricted three body problem. They proved to be the most unreliable at mean motion resonances. The observed distribution of the outer belt asteroids could not be fully explained within the framework of the elliptic restricted three body problem only. A study to understand the behavior of orbits at mean motion resonances in the presence of additional perturbations is suggested. Author

THE MORPHOLOGIES OF DISTANT RADIO GALAXIES Ph.D. Thesis
Michael Anthony Rigler 1992 162 p
Avail: Univ. Microfilms Order No. DA9312216

Multicolor line and continuum images of a complete sample of 13 3C radio galaxies at 0.8 less than z less than 1.3, spanning the range 2500 A to 1 micrometer in the rest frame, are presented and analyzed. Quantitative analysis of these images shows that the infrared images are less elongated than those at optical wavelengths and show only a much weaker 'alignment effect' with the radio source axis. The quadrupole moment$ show a progressive reduction from short to long wavelengths, as expected if a symmetric component dominates at infrared wavelengths. A spectral decomposition based on these moments suggests that the aligned component probably has a roughly flat spectral energy distribution (f(sub v) approximately equals 0 to -1) while the symmetric red component that dominates in the infrared probably has a spectral energy distribution similar to that of a gE galaxy. In typical 3C galaxies at z = 1, the active aligned component contributes 10 percent of the infrared light. While more active objects have a larger contamination, these generally modest components are insufficient to perturb significantly either the scatter in, or the continuity of, the observed K-z relation. A model surface fitting analysis of the reddest member of the sample, 3C 65, and of another red galaxy, 3C 437 (z = 1.480), shows that the infrared surface brightness profiles are well fit by a deVaucouleurs r(exp 1/4) law characteristic of giant ellipticals, with characteristic photometric parameters comparable to those of brightest cluster members and low-redshift radio galaxies for standard cosmologies. Several of these radio galaxies are accompanied by small red companion galaxies that are prominent on our infrared images at random position angles relative to the radio axis. These are interpreted as representing a conventional trigger for the radio sources. There is a preference for these companions to be associated with the bluest, most aligned, and generally most active objects. Author

ORIGINS OF SOLAR SYSTEMS WORKSHOP: THE ORIGIN, EVOLUTION, AND DETECTABILITY OF SHORT PERIOD COMETS Final Report

S. Alan Stern 30 Jun. 1993 44 p Workshop held in San Antonio, TX, 30 Jun. 1993
(SwRI Proj. 15-5296)
(NASA-CR-194255; NAS 1.26:194255) Avail: CASI HC A03/MF A01

The origin of the short period comets (SPC) (periods less than 200 years), the dynamical formation of their present reservoir(s), the cause and rate of their transport to the inner planetary region where they can be detected, and the magnitude of selection effects in their discovery are important research questions directly coupled to the goals of understanding the origin and evolution of the Solar System. To address these questions in an intensive way, an interdisciplinary, five month long Workshop from Jan. to May 1993 at Southwest Research Institute (SwRI) in San Antonio was convened. The goal of this Workshop was to advance the state of understanding about the origins, dynamical evolution, and present location of short period comets and their reservoir(s). For individual titles, see N94-11629 through N94-11629.

THE LONG-TERM DYNAMICAL BEHAVIOR OF SHORT-PERIOD COMETS

Harold F. Levison and Martin J. Duncan (Queens Univ., Kingston, Ontario.) *In its* Origins of Solar Systems Workshop: The Origin, Evolution, and Detectability of Short Period Comets 30 Jun. 1993 p 1-36 (For primary document see N94-11628 01-90)
Avail: CASI HC A03/MF A01

The orbits of the known short-period comets under the influence of the Sun and all the planets except Mercury and Pluto are numerically integrated. The calculation was undertaken in order to determine the dynamical lifetimes for these objects as well as explaining the current orbital element distribution. It is found that a comet can move between Jupiter-family and Halley-family comets several times in its dynamical lifetime. The median lifetime of the known short-period comets from the time they are first injected into a short-period comet orbit to ultimate ejection is approximately 50,000 years. The very flat inclination distribution of Jupiter-family comets is observed to become more distended as it ages. The only possible explanation for the observed flat distribution is that the comets become extinct before their inclination distribution can change significantly. It is shown that the anomalous concentration of the argument of perihelion of Jupiter-family comets near 0 and 180 deg is a direct result of their aphelion distance being close to 5.2AU and the comet being recently perturbed onto a Jupiter-family orbit. Also the concentration of their aphelion near Jupiter's orbit is a result of the conservation of the Tisserand invariant during the capture process. Author (revised)

THE SOLUTIONS OF COSMIC STRING LOOP EQUATION IN EXPANDING UNIVERSE

Xinzhou Li and Jianzu Zhang (Shanghai Normal Univ., China.) Sep. 1992 9 p
(DE93-619717; IC-92/285) Avail: CASI HC A02/MF A01 (US Sales Only)

The cosmic string loop equation is studied analytically during the radiation-dominated era in the Robertson-Walker universe. If the loops expand with Hubble flow at the time of formation of loops, the cosmic string loops occur always collapsing. We also discuss the initial radii R(sub s)(t*) dependence of the lifetime tau(sub s) without considering the oscillations, as a first approximation, where t* denotes the time of formation of loops. We find that the lifetime factor gamma = c tau(sub s)/R(sub s)(t*) is (pi)/2 in the little initial radius limit. DOE

THE MAGNETIC FIELD OF ROTATING BODIES

F. I. Mikhail (Ain Shams Univ., Cairo, Egypt.), M. I. Wanas (Cairo Univ., Giza, Egypt.), and A. M. Eid Sep. 1991 18 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-619769; IC-91/253) Avail: CASI HC A03 (US Sales Only)

The paper discusses the possibility of interpreting the magnetic fields of astronomical bodies in the framework of a unified field theory. Using one of the solutions of the generalized field theory, a direct relation between the polar magnetic field, the angular velocity and the gravitational potential of the body considered, is obtained. The model used for applications has spherical symmetry. The predictions of the theoretical formula, obtained from the model, are compared with available observational data, and with the empirical relation of Blackett. The theoretical formula gives a possible interpretation of a seed magnetic field which will develop and produce the largescale magnetic field observed for celestial objects. The formula shows that the field may be generated as a result of the rotation of the massive object. DOE

SUBMISSION OF EARTH-BASED RING OCCULTATION OBSERVATIONS TO THE NASA PLANETARY DATA SYSTEM RINGS DISCIPLINE NODE Technical Report, 1 Jul. 1992 - 30 Jun. 1993

Richard G. French 2 Aug. 1993 40 p
(Grant NAG2-814)
(NASA-CR-193469; NAS 1.26:193469) Avail: CASI HC A03/MF A01

This is a technical report summarizing our progress in our program of contributing high quality Earth-based occultation observations to NASA's Planetary Data System (PDS) Rings Node. During our first year of funding, we selected five data sets for eventual inclusion in the PDS Rings Node. These were Uranus occultation observations obtained by the PI and co-workers from the IRTF of event stars U34 (26 April 1986), U1052 (5 May 1988), U65 (21 June 1990), U7872 (25 June 1991), and U7808 (28 June 1991). In our original proposal, we described four tasks: data sets to a common format; documentation of the occultation observations and associated calibrations; calculation of the occultation geometry for each event; establish prototype PDS templates. As discussed in our renewal proposal, submitted 8 June 1993, we have completed the first three tasks, and are working on the fourth. As an indication of our progress to date, we provide information about each of the data sets, their formats, the documentation, and the method used for reconstructing the occultation geometry. COORDINATED RADIO, ELECTRON, AND WAVES EXPERIMENT (CREWE) FOR THE NASA COMET RENDEZVOUS AND ASTEROID FLYBY (CRAF) INSTRUMENT Final Technical Report

Jack D. Scudder 1992 80 p

(Grant NAG5-983)
(NASA-CR-194376; NAS 1.26:194376) Avail: CASI HC A05/MF A01

The Coordinated Radio, Electron, and Waves Experiment (CREWE) was designed to determine density, bulk velocity and temperature of the electrons for the NASA Comet Rendezvous and Asteroid Flyby Spacecraft, to define the MHD-SW IMF flow configuration; to clarify the role of impact ionization processes, to comment on the importance of anomalous ionization phenomena (via wave particle processes), to quantify the importance of wave turbulence in the cometary interaction, to establish the importance of photoionization via the presence of characteristic lines in a structured energy spectrum, to infer the presence and grain size of significant ambient dust column density, to search for the theoretically suggested 'impenetrable' contact surface, and to quantify the flow of heat (in the likelihood that no surface exists) that will penetrate very deep into the atmosphere supplying a good deal of heat via impact and charge exchange ionization. This final report provides an instrument description, instrument test plans, list of deliverables/schedule, flight and support equipment and software schedule, CREWE accommodation issues, resource requirements, status of major contracts, an explanation of the non-NASA funded efforts, status of EIP and IM plan, descope options, and Brinton questions. ANALYSIS OF INTERSTELLAR FRAGMENTATION STRUCTURE BASED ON IRAS IMAGES Final Report, 1 Jun. 1987 - 31 May 1989
John M. Scalo 31 May 1989 6 p
(Contract JPL-958003)
(NASA-CR-193518; NAS 1.26:193518) Avail: CASI HC A02/MF A01

The goal of this project was to develop new tools for the analysis of the structure of densely sampled maps of interstellar star-forming regions. A particular emphasis was on the recognition and characterization of nested hierarchical structure and fractal irregularity, and their relation to the level of star formation activity. The panoramic IRAS images provided data with the required range in spatial scale, greater than a factor of 100, and in column density, greater than a factor of 50. In order to construct a densely sampled column density map of a cloud complex which is both self-gravitating and not (yet?) stirred up much by star formation, a column density image of the Taurus region has been constructed from IRAS data. The primary drawback to using the IRAS data for this purpose is that it contains no velocity information, and the possible importance of projection effects must be kept in mind. Derived from text

GIOTTO DATA ANALYSIS: ELECTRON PLASMA AND HEAVY ION COMPOSITION MEASUREMENTS AT COMET HALLEY Final Report, 1 May 1988 - 31 Aug. 1991
Robert P. Lin 18 Mar. 1992 5 p
(Grant NAGw-1298)
(NASA-CR-193587; NAS 1.26:193587) Avail: CASI HC A01/MF A01

This investigation involved the analysis of electron plasma and heavy ion composition measurements made by the COPERNIC (COmplete Positive ion, Electron, and Ram Negative Ion measurements near Comet Halley) plasma experiment during the close fly-by of Halley by the European Space Agency's Giotto spacecraft. The experiment provided measurements of the full 3-dimensional distribution of 10 eV-30 keV electrons, and mass analysis of cold cometary ions from 10-210 amu. The analysis of the COPERNIC data has yielded some remarkable results, including: The discovery of negatively charged ions in the inner coma; the discovery of far heavier (mass is greater than 50 amu) ions than predicted, dominated by complex molecular ions made up of C, H, O, and N; the discovery of an adiabatic heating effect on electrons from the compression of the solar wind plasma; the identification of several organic and sulfur bearing ions; and the discovery of a new 'mystery region' where electrons are accelerated to high energies. These discoveries were in addition to the detailed analysis of 'expected' features at Comet Halley. Although this grant has expired, analysis continues on the data at a low (unfunded) level, and it is expected that more significant results will be obtained. A bibliography of the papers resulting from this research is attached, and a copy of each paper is included. Derived from text

LUNAR CAMPSITE CONCEPT: SPACE TRANSFER CONCEPTS AND ANALYSIS FOR EXPLORATION MISSIONS
May 1991 59 p
(Contract NAS8-37857)
(NASA-CR-192602; NAS 1.26:192602) Avail: CASI HC A04/MF A01

The lunar Campsite concept responds to a perceived need to identify early manned science and exploration missions that require minimal initial funding. The Campsite concept defers the build-up of many infrastructure components without escalating total program costs. The lunar Campsite has been sized nominally for four crew for 42 days (1 lunar night and 2 lunar days), but can be modified to span two lunar nights up to 60 days.

Total mission fulfillment requires five Earth-to-LEO launches, four (100 mt class launch vehicle) for the two vehicle assemblies and one (PLS or NSTS) for the crew. The lunar Campsite mission mode is tandem direct using a booster stage and a lander stage. The booster is separated from the lander after the TLI burn and is expended into the Earth's atmosphere. In the Campsite mode, the lander lands on the surface not to be returned. In the crew delivery mode, the lander is guided to a precision landing about 500 m from the Campsite, and with enough propellant to return the crew to Earth. The Campsite consists of a habitat and airlock, body mounted radiators with a surface shield, sun tracking solar arrays, and an Earth-tracking high-gain antenna. The CV is very similar to the campsite delivery vehicle. The CV does not, however, have radiators or solar arrays. The vehicle stacks are essentially common in that they utilize the same structure system and engines, the same propellant tanks, the same 'cut-out' in which the CRV and payloads are incorporated, and the same RCS locations. The booster and lander stage propellant tank propellant capacities are identical and have margins which would allow additional fueling for propulsive capture of the boost stage into Earth orbit. This contractual study was performed to identify Campsite and vehicle interfaces and vehicle requirements, and to surface issues related to the integration of the Campsite and LTV's. PHOTOCHEMICAL MODELLING OF VENUS CLOUDS USING PIONEER VENUS DATA Final Report
Michael B. McElroy 24 Apr. 1985 22 p
(Grant NAG2-264)
(NASA-CR-194108; NAS 1.26:194108) Avail: CASI HC A03/MF A01

In order to understand the evolution of water on Venus, we must know the hydrogen escape flux as a function of the tropospheric water abundance. We have studied the connection between total stratospheric hydrogen and exobase hydrogen available to non-thermal escape processes and examined the details of the photochemical trap for water at the Venus cloud tops. Our immediate goal is to calculate the stratospheric water abundance as a function of the tropospheric water abundance. Photochemical production of H2SO4 acts as a sink for both water and sulfur and is capable of keeping stratospheric abundances low if a proper balance exists between the tropospheric abundances. If production of H2SO4 were the only sink for H2O and SO2, the excess in tropospheric abundance of one over the other would reach the stratosphere, and the functional dependence of stratospheric H2O on tropospheric H2O would be linear near the present state. On Venus, however, sulfuric acid condenses at cloud top temperatures and the resulting aerosols can absorb additional water of hydration. This complicates the water budget, increasing the efficiency of sulfur as a sink for water. We have investigated the balance between tropospheric H2O and SO2 and how delicate the balance is. Our major conclusions from this work are the following: (1) H2O and SO2 are mutually limiting if proper tropospheric balance is maintained; (2) changes in tropospheric abundances on the order of 5 ppm are significant; and (3) changes in mixing rates near the cloud tops can cause dramatic changes in SO2 without causing dramatic changes in H2O. EVOLUTION OF STEEP MARTIAN SLOPES Ph.D. Thesis
Robert John Sullivan, Jr. 1992 204 p
Avail: Univ. Microfilms Order No. DA9307143

The physical properties and evolution of steep slopes on the planet Mars are examined. Where martian slopes are steepest and of greatest relief, the slope morphology is distinctive and characterized by regular, alternating spurs and gullies. Previous workers identified these martian gullies as dry debris avalanche chutes, partially because a nonspecific 'dry mass-wasting' explanation seemed compatible, initially, with current surface conditions. An evacuated avalanche chute provides the opportunity to back analyze the stability of the mobile layer of the chute at the time of its failure. For the martian slope problem a new stability back-analysis technique was developed which incorporates the third dimension (chute width) into the back-analysis calculation, allowing unambiguous determination of the average cohesion and angle of internal friction of the mobile layer. A series of trials was performed to investigate the effects of gravitational acceleration, average slope angle, and average mobile layer density, cohesion, and angle of internal friction on the size and shape of the transverse chute cross-section. Results indicate that: (1) variations in density, gravitational acceleration, and cohesion affect the overall size of the cross-section but not its width:depth ratio, and (2) the contrast between average slope angle and angle of internal friction is most influential on the width:depth ratio of the cross-section. The difference between these two parameters is inversely proportional to the width:depth ratio. Application of the three-dimensional back-analysis technique to proposed martian avalanche chutes yields values of cohesion and angle of internal friction of the mobile layers that are similar mechanically (without genetic implications) to those of terrestrial glacial till, a poorly sorted material with moderate inter-grain cohesion, or lunar soils under normal stresses representative of (lunar) depths of between ten and twenty meters. Material of these strengths is not capable of supporting long, steep martian slopes visible on Viking Orbiter images. These results imply that weathering and weakening of initially stronger martian slope materials penetrated to depths of tens of meters before downslope failure of weathered material occurred (creating the observed avalanche chutes). Dissert. Abstr.

WAVE STRUCTURE IN PLANETARY RINGS Ph.D. Thesis
Linda Joyce Horn 1992 276 p
Avail: Univ. Microfilms Order No. DA9310920

Planetary rings contain a wealth of wavelike structure that is driven by gravitational resonance interactions with nearby satellites. Wave behavior is a powerful tool for estimating physical ring parameters that are key to our understanding of ring origin and evolution. A new technique, utilizing the Burg autoregressive power spectral algorithm, was developed for probing the physical characteristics of rings and for detecting waves that are not otherwise visible. Data from the Voyager photopolarimeter (PPS) stellar occultations by the rings of Saturn, Uranus, and Neptune and the Voyager radio science (RSS) occultation by Saturn's rings were used. Local surface mass density estimates are obtained from the dispersion of 40 spiral density waves in Saturn's A ring, including 10 weaker waves not previously analyzed. Surface mass densities vary from 20 to 60 gm sq cm. Increasing optical depth is not correlated with increasing surface mass density, especially after the Keeler gap, suggesting that ring particle size and composition are not uniform throughout the A ring. Saturn's A ring mass is reestimated using the surface mass densities and is 5.2 +/- 1.3 x 10(exp 21) gm. The wakes of Saturn's satellite Pan are not short timescale phenomena because the effects of Pan's gravitational perturbations persist for more than one Pan encounter. Four additional Pan wakes were discovered at longitudes greater than 360 deg. Collective effects such as collisions modify the wake dispersion more extensively at greater longitudes. Pan is the dominant mass in the Encke gap. A spiral density wave was detected inside the Uranian delta ring. Upper and lower bounds were estimated for the surface mass density of the delta ring 5 less than or equal to sigma less than or equal to 10 gm/sq cm, the viscosity 10 less than or equal to nu less than or equal to 40 sq cm/sec, and the local ring height 7 less than or equal to h less than or equal to 20 m. These values are comparable to the corresponding values at Saturn. An Adams ring arc and the Leverrier ring were detected in the PPS data. The Adams arc is 43 km wide with an equivalent depth of 0.77 +/- 0.13 km. The Leverrier ring is 113 km in wide with an equivalent depth of 0.7 +/- 0.2 km. Values for the Adams ring arc are consistent with Voyager ultraviolet spectrometer and ground-based numbers while the Leverrier ring was not detected in these data sets. Dissert. Abstr.

THEORETICAL STUDIES OF THE RADAR PROPERTIES OF THE ICY GALILEAN MOONS OF JUPITER Final Report

Von R. Eshleman Jul. 1993 57 p
(Grant NAGw-1964)
(NASA-CR-193407; NAS 1.26:193407) Avail: CASI HC A04/MF A01

The icy Galilean satellites of Jupiter - Europa, Ganymede, and Callisto - have unusual radar scattering properties compared with those of the terrestrial planets or Earth's Moon. There are three main features of the data that distinguish these targets: (1) the radar cross-section normalized by the geometrical cross-section is an order of magnitude larger than that of any terrestrial planet; (2) the reflected power is almost evenly distributed between two orthogonal polarizations with more power being returned in the same circular polarization as was transmitted whereas virtually all of the power returned from the terrestrial planets is contained in the opposite circular polarization to the one that was transmitted; and (3) the echo power spectra have a broad shape indicating a nearly uniformly radar-bright surface in contrast to the spectra from the terrestrial planets that contain a strong quasi-specular component from the vicinity of the sub-radar point and very little reflected power from the rest of the surface. The normalized radar cross-sections decrease as the areal water ice coverage decreases from Europa to Ganymede to Callisto. Recently, radar echoes from the polar caps of Mars and Mercury, and from Saturn's satellite Titan imply similarly strong cross-sections and have classically unexpected polarization properties and it is also thought that this is due to the presence of ice on the surface. A model called the radar glory model is analyzed and it is shown that the main features of the radar echoes calculated from this model agree well with the observations from all three icy Galilean satellites. This model involves long radar paths in the ice below the surface and special structures in which the refractive index decreases abruptly at a hemispherical boundary. It is not known whether such structures exist or how they could be created, but possible scenarios can be imagined such as the formation of an impact crater followed by deposition of a frost layer followed by a resurfacing event in which a layer of solid ice is placed above the layer of frost. Regardless of the exact geophysical processes required to create such structures, the superior ability of this model to account for all of the important observations with very few adjustable parameters and with no ad hoc assumptions is a compelling argument in support of at least the electromagnetic model. The key features of the electromagnetic model are multiple subsurface scattering events, total internal reflection, and a low degree of randomness imposed on a deterministic geometry that strongly favors backscattering.

MOESSBAUER SPECTROSCOPY OF THE SNC METEORITE ZAGAMI Abstract Only c90

D. P. Agerkvist and L. Vistisen *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 1-2 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

We have performed Mossbauer spectroscopy on two different pieces of the meteorite Zagami belonging to the group of SNC meteorites. In one of the samples we found a substantial amount of olivine inter grown with one kind of pyroxene, and also another kind of pyroxene very similar to the pyroxene in the other sample we examined. Both samples showed less than 1 percent of Fe(3+) in the silicate phase. The group of SNC meteorites called shergottites, to which Zagami belongs, are achondrites whose texture, mineralogy and composition resembles those of terrestrial diabases. The results from the investigation are presented.

PRODUCTION OF ELECTRONIC GRADE LUNAR SILICON BY DISPROPORTIONATION OF SILICON DIFLUORIDE Abstract Only

William N. Agosto *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 3-4 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Waldron has proposed to extract lunar silicon by sodium reduction of sodium fluorosilicate derived from reacting sodium fluoride with lunar silicon tetrafluoride. Silicon tetrafluoride is obtained by the action of hydrofluoric acid on lunar silicates. While these reactions are well understood, the resulting lunar silicon is not likely to meet electronic specifications of 5 nines purity. Dale and Margrave have shown that silicon difluoride can be obtained by the action of silicon tetrafluoride on elemental silicon at elevated temperatures (1100-1200 C) and low pressures (1-2 torr). The resulting silicon difluoride will then spontaneously disproportionate into hyperpure silicon and silicon tetrafluoride in vacuum at approximately 400 C. On its own merits, silicon difluoride polymerizes into a tough waxy solid in the temperature range from liquid nitrogen to about 100 C. It is the silicon analog of teflon. Silicon difluoride ignites in moist air but is stable under lunar surface conditions and may prove to be a valuable industrial material that is largely lunar derived for lunar surface applications. The most effective driver for lunar industrialization may be the prospects for industrial space solar power systems in orbit or on the moon that are built with lunar materials. Such systems would require large quantities of electronic grade silicon or compound semiconductors for photovoltaics and electronic controls. Since silicon is the most abundant semimetal in the silicate portion of any solar system rock (approximately 20 wt percent), lunar silicon production is bound to be an important process in such a solar power project. The lunar silicon extraction process is discussed.

RATES OF FLUVIO-THERMAL EROSION ON MARS Abstract Only

J. Aguirre-Puente, Francois M. Costard (Centre National de la Recherche Scientifique, Caen, France.), and R. Posado-Cano *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 5-6 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

In order to get some ideas about the order of magnitude of fluvio-thermal recession rate, a mathematical thermal model for Martian outflow channels is proposed. This model corresponds to a system undergoing a permanent thermal regime where the surface temperature is constant and equal to the phase change temperature (due to the immediate removal of melted materials). This is an ablation model. For its application, estimations of the heat transfer coefficient h and thermal flux q are necessary. Determination of these coefficients needs the calculation of dimensionless numbers (Reynolds, Prandtl, and Nusselt), and the consideration of turbulent regime of the flow.

GIANT IMPACT-INDUCED ATMOSPHERIC BLOW-OFF Abstract Only

Thomas J. Ahrens *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 7-8 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The relationship between the present atmospheres of the Earth, Venus, and Mars and the earliest (primordial) atmospheres which surrounded these planets is discussed. The termination of the co-accretion of an atmosphere results from at least three different mechanisms, and these mechanisms are presented. To calculate the energy, and hence, approximate planetesimal size, such that upon impact the entire planetary atmosphere is blown off, a different approach than previous efforts is employed, and a shock wave that is entirely propagated within a terrestrial planet is considered.

DISPERSION OF THE RATIOS OF COSMOGENIC ISOTOPES OF NOBLE GASES IN CHONDRITES OF DIFFERENT COSMIC-RAY EXPOSURE AGES Abstract Only **c90**
V. A. Alexeev *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 9-10 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The dispersion of ratios of (He-3/Ne-21)c and (Ne-22/Ne-21)c depending on the cosmic-ray exposure ages of meteorites is analyzed. The dispersion is increased as age decreases. This effect may be stipulated by presence of a more significant portion of meteorites of small preatmospheric sizes among meteorites of small radiation ages in comparison to meteorites of higher exposure age. PECULIARITIES OF DISTRIBUTIONS OF THE COSMIC-RAY EXPOSURE AGES OF H CHONDRITE FALLS AND FINDS Abstract Only **c90**
V. A. Alexeev *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 11-12 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Well known peak in the distribution of the cosmic-ray exposure ages of H chondrites at 6-7 My can be employed as mark in comparison of different populations of H chondrites. It is found the age corresponding to maximum of peak for non-Antarctic falls is higher by (15+/-5) percent of this for non-Antarctic finds. Antarctic H chondrites occupy intermediate position. This effect is probably due to process of weathering. Derived from text

MORPHOLOGY OF LARGE IMPACT CRATERS AND BASINS ON VENUS: IMPLICATIONS FOR RING FORMATION Abstract Only
Jim S. Alexopoulos and William B. McKinnon *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 15-16 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

A nearly complete examination of the Magellan radar data for the Venusian surface reveals 72 unequivocal peak-ring craters and 4 larger structures that we interpret to be multiringed. This report updates our earlier studies and that of the Magellan team. The general morphology of peak-ring craters, decreasing ring diameter ratio trends with increasing crater diameter, and the general size-morphology progression from complex central-peak crater to peak-ring crater on Venus and the terrestrial planets suggest similar processes of peak-ring formation. Observations are consistent with a model of dynamic collapse, downward and outward, of an unstable central peak to form a ring. We interpret the four larger ringed structures (Klenova, Lise Meitner, Mead, and Isabella) to be morphologically similar to the Orientale Basin on the Moon, and thus, true multiringed basins. Avail: CASI HC A01/MF A06

Maturity, which is a measure of the time lunar soils have been in the upper approximately 1 mm of the surface, is correlated with changes in the soils' optical properties. Mature soil is darker and somewhat redder than immature soil of the same composition, and features in the reflectance spectrum become more subdued with increasing maturity. The maturation process also involves accumulation of agglutinitic glass and submicroscopic metallic iron particles. We have produced submicrometer iron metal blebs on the surface and within glass and mineral grains by the method of high-temperature reduction. This technique has permitted the determination of optical changes in samples much simpler than lunar soil, and offers a useful tool with which to investigate the maturation process. COLD PRESS SINTERING OF SIMULATED LUNAR BASALT Abstract Only **c31**
D. A. Altemir *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 23-24 Sponsored by NASA. Washington (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

In order to predict the conditions for which the lunar regolith may be adequately sintered, experiments were conducted in which samples of simulated lunar basalt (MLS-1) were pressed at high pressures and then heated in an electric furnace. This sintering process may be referred to as cold press sintering since the material is pressed at room temperature. Although test articles were produced which possessed compressive strengths comparable to that of terrestrial concrete, the cold press sintering process requires very high press pressures and sintering temperatures in order to achieve that strength. Additionally, the prospect of poor internal heat transfer adversely affecting the quality of sintered lunar material is a major concern. Therefore, it is concluded that cold press sintering will most likely be undesirable for the production of lunar construction materials. Derived from text

GENERAL OVERVIEW OF AN INTEGRATED LUNAR OXYGEN PRODUCTION/BRICKMAKING SYSTEM Abstract Only **c31**
D. A. Altemir *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 25-26 Sponsored by NASA. Washington (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

On the moon, various processing systems would compete for the same resources, most notably power, raw materials, and perhaps human attention. Therefore, it may be advantageous for two or more processes to be combined such that the integrated system would require fewer resources than separate systems working independently. The synergistic marriage of two such processes--lunar oxygen production and the manufacture of bricks from sintered lunar regolith--is considered. Derived from text

THERMODYNAMICS OF LUNAR ILMENITE REDUCTION Abstract Only c77
B. H. Altenberg, H. A. Franklin, and C. H. Jones *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 27-28 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

With the prospect of returning to the moon, the development of a lunar occupation would fulfill one of the goals of the Space Exploration Initiative (SEI) of the late 1980's. Processing lunar resources into useful products, such as liquid oxygen for fuel and life support, would be one of many aspects of an active lunar base. ilmenite ($FeTiO_3$) is found on the lunar surface and can be used as a feed stock to produce oxygen. Understanding the various ilmenite-reduction reactions elucidates many processing options. Defining the thermodynamic chemical behavior at equilibrium under various conditions of temperature and pressures can be helpful in specifying optimal operating conditions. Differences between a previous theoretical analysis and experimentally determined results has sparked interest in trying to understand the effect of operating pressure on the hydrogen-reduction-of-ilmenite reaction. Various aspects of this reduction reaction are discussed. Derived from text

INTERSTELLAR GRAPHITE IN MURCHISON: CONTINUED SEARCH FOR ISOTOPICALLY DISTINCT COMPONENTS Abstract Only c27
Sachiko Amari, Ernst Zinner, and Roy S. Lewis (Chicago Univ., IL.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 29-30 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

We have measured C-, N-, and O-isotopic ratios of individual graphite grains from the Murchison density fractions KFB1 (2.1-2.15 g/cc) and KFC1 (2.15 -2.20 g/cc). According to the C-isotopic composition, KFC1 consists of two populations: one has light C while the other has heavy C. In addition to these two populations, KFB1 also contains grains whose C-isotopic ratios are approximately normal. In view of these isotopic distributions, it is difficult to understand why the Kr-isotopic compositions of these two separates are so different. In contrast to the lighter density fractions KE1 (1.6-2.05 g/cc) and KFA1 (2.05-2.10 g/cc), the separates KFB1 and KFC1 do not seem to contain many grains with significant O-18 excess. FOURIER DOMAIN TARGET TRANSFORMATION ANALYSIS IN THE THERMAL INFRARED Abstract Only c43
D. L. Anderson *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 31-32 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Remote sensing uses of principal component analysis (PCA) of multispectral images include band selection and optimal color selection for display of information content. PCA has also been used for quantitative determination of mineral types and abundances given end member spectra. The preliminary results of the investigation of target transformation PCA (TTPCA) in the fourier domain to both identify end member spectra in an unknown spectrum, and to then calculate the relative concentrations of these selected end members are presented. Identification of endmember spectra in an unknown sample has previously been performed through bandmatching, expert systems, and binary classifiers. Both bandmatching and expert system techniques require the analyst to select bands or combinations of bands unique to each endmember. Thermal infrared mineral spectra have broad spectral features which vary subtly with composition. This makes identification of unique features difficult. Alternatively, whole spectra can be used in the classification process, in which case there is not need for an expert to identify unique spectra. Use of binary classifiers on whole spectra to identify endmember components has met with some success. These techniques can be used, along with a least squares fit approach on the endmembers identified, to derive compositional information. An alternative to the approach outlined above usese target transformation in conjunction with PCA to both identify and quantify the composition of unknown spectra. Preprocessing of the library and unknown spectra into the fourier domain, and using only a specific number of the components, allows for significant data volume reduction while maintaining a linear relationship in a Beer's Law sense. The approach taken here is to iteratively calculate concentrations, reducing the number of endmember components until only non-negative concentrations remain. Derived from text

LINEAMENT ANALYSIS AND TECTONIC INTERPRETATION FOR THE THARSIS REGION Abstract Only
Robert Anderson *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 33 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The Tharsis region of Mars is critical to any study of Martian tectonics. This region (65 N and 65 S latitude; 45 W to 157.5 W longitude) is characterized by an asymmetrical dome-shaped topographic high approximately 8000 km across. Affecting over 25 percent of the surface area, this region has been the center of most of the major tectonic and volcanic activity that has taken place on the Martian surface. Lineament studies are the primary tool available for studying tectonic processes on terrestrial planets such as Mars. At least three major lineament systems can be delineated in the Tharsis region; north-south and east-west trending lineament systems are superimposed on an older northwest trending lineament system. Four centers of uplift have been identified based on the occurrence of radial fracture patterns. Preliminary results indicate that the formation of the Tharsis Dome may not have resulted from a single uplift event, but may instead have resulted from as many as four uplift events. The northwest trending fracture may represent a pre-existing zone of weakness which contributed to the early formation of the Tharsis Dome. The 1:2,000,000 scale photo mosaic maps of Mars were examined and lineaments were identified. The end points of each lineament were measured and recorded in an X-Y reference coordinate frame. DESCRIPTIONS AND PRELIMINARY INTERPRETATIONS OF CORES RECOVERED FROM THE MANSON IMPACT STRUCTURE (IOWA) Abstract Only c46
R. R. Anderson, B. J. Witzke, J. B. Hartung, E. M. Shoemaker (Geological Survey, Flagstaff, AZ.), and D. J. Roddy (Geological Survey, Flagstaff, AZ.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 35-36 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

A core drilling program initiated by the Iowa Geological Survey Bureau and U.S. Geological Survey in 1991 and 1992 collected 12 cores totalling over 1200 m from the Manson Impact Structure, a probable K-T boundary structure located in north-central Iowa. Cores were recovered from each of the major structural terranes, with 2 cores (M-3 and M-4) from the Terrace Terrane, 4 cores (M-2, M-2A, M-6, and M-9) from the Crater Moat, and 6 cores (M-1, M-5, M-7, M-8, M-10, and M-11) from the Central Peak. These supplemented 2 central peak cores (1-A and 2-A) drilled in 1953. The cores penetrated five major impact lithologies: (1) sedimentary clast breccia; (2) impact ejecta; (3) central peak crystallite rocks; (4) crystalline clast breccia with sandy matrix; and (5) crystallite clast breccia with a melt matrix. Descriptions and preliminary interpretations of these cores are presented. Derived from text

MEASUREMENTS OF COSMOGENIC NUCLIDES IN LUNAR ROCK 64455 Abstract Only
J. R. Arnold, C. P. Kohl, K. Nishiizumi (California Univ., Berkeley.), M. W. Caffee (Lawrence Livermore National Lab., CA.), R. C. Finkel (Lawrence Livermore National Lab., CA.), and J. R. Southon (Lawrence Livermore National Lab., CA.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 39-40 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Eleven samples were ground from the glass coated surface of lunar rock 64455,82 with an average depth resolution of 50 microns and were measured for Be-10, Al-26, and Cl-36 using AMS (accelerator mass spectrometry). Results show no evidence of SCR (solar cosmic ray) effects. The flat cosmogenic nuclide profiles and activity levels are consistent with a 2 My exposure history for the rock and a sample location on the bottom of the rock. These AMS measurements are some of the most precise ever obtained for these three nuclides. This precision and the demonstrated fine depth resolution will enable us to conduct a number of detailed studies of depth effects in lunar and meteoritic samples, including investigating SCR effects in the surface exposed top of the glass coating of 64455 and possibly in the underlying rock. CARBON IN WEATHERED ORDINARY CHONDRITES FROM ROOSEVELT COUNTY Abstract Only c90
R. D. Ash and C. T. Pillinger (Open Univ., Milton, England.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 43-44 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

A suite of Roosevelt County ordinary chondrites of known terrestrial age have been analyzed for carbon content and isotopic composition. Initial results indicate that significant carbon contamination is evident only in samples with a terrestrial age greater than 40 ka. These samples are of weathering grade D and E and contain three times more carbon than the less weathered samples. The soil in which they were preserved has a carbon content of ca. 1.5 percent. Over 200 meteorites have been recovered from a series of soil depleted areas of New Mexico and West Texas. Most have been recovered from blowouts near Clovis in Roosevelt County (RC) on the high plains of New Mexico. The mineralogical and petrologic Al effects of weathering upon these samples have been studied previously and show that the degree of weathering is largely depend ant upon the terrestrial residence time. The study was undertaken to determine the effects of prolonged exposure to the soil and climate of Roosevelt County upon ordinary chondrites in the hope that this will enable a better understanding of the problems associated with the collection of meteoritic falls. A suite of ten grade 4 to 6 H, L, and LL ordinary chondrites were analyzed for carbon content and isotopic composition. Derived from text

EJECTING BASALTIC ACHONDRITES FROM VESTA: HYDRODYNAMICAL IMPACT MODELS Abstract Only c90
E. Asphaug, H. J. Melosh, and E. Ryan (Planetary Science Inst., Tucson, AZ.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 45-46 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Vesta is a large asteroid whose crust is mostly basaltic. Spectral heterogeneity suggests a sizable olivine feature which may be explained as impact excavation. The spectral data probably show a localized feature approximately 200 km in diameter or a diffuse feature approximately 400 km in diameter. Lightcurve irregularities suggest heterogeneity on a similar scale. This heterogeneity may represent the crater bowl, the extent of its ejecta deposit, or indeed something unrelated to cratering. In any case, drawing direct inferences about the state of Vesta's surface on the basis of these observations involves substantial speculation. We are still far from understanding the boundary between cratering and catastrophic disruption, particularly on targets for which strength and self-gravity both matter. But we are now able to model the underlying physical process -- dynamic fragmentation -- accurately with fragmentation hydrocodes such as SALE 2D and SPH3D. We present several impact scenarios for Vesta; our study is similar to a previous impact model for the formation of Stickney crater on Phobos. We illustrate the effects of impactors of different sizes and velocities, and the effect of gravity and structural inhomogeneity. Derived from text

VENUS SMALL VOLCANO CLASSIFICATION AND DESCRIPTION Abstract Only
J. C. Aubele *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 47-48 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The high resolution and global coverage of the Magellan radar image data set allows detailed study of the smallest volcanoes on the planet. A modified classification scheme for volcanoes less than 20 km in diameter is shown and described. It is based on observations of all members of the 556 significant clusters or fields of small volcanoes located and described by this author during data collection for the Magellan Volcanic and Magmatic Feature Catalog. This global study of approximately 10 exp 4 volcanoes provides new information for refining small volcano classification based on individual characteristics. Total number of these volcanoes was estimated to be 10 exp 5 to 10 exp 6 planetwide based on pre-Magellan analysis of Venera 15/16, and during preparation of the global catalog, small volcanoes were identified individually or in clusters in every C1-MIDR mosaic of the Magellan data set. Basal diameter (based on 1000 measured edifices) generally ranges from 2 to 12 km with a mode of 34 km, and follows an exponential distribution similar to the size frequency distribution of seamounts as measured from GLORIA sonar images. This is a typical distribution for most size-limited natural phenomena unlike impact craters which follow a power law distribution and continue to infinitely increase in number with decreasing size. Using an exponential distribution calculated from measured small volcanoes selected globally at random, we can calculate total number possible given a minimum size. The paucity of edifice diameters less than 2 km may be due to inability to identify very small volcanic edifices in this data set; however, summit pits are recognizable at smaller diameters, and 2 km may represent a significant minimum diameter related to style of volcanic eruption. Guest, et al, discussed four general types of small volcanic edifices on Venus: (1) small lava shields; (2) small volcanic cones; (3) small volcanic domes; and (4) scalloped margin domes ('ticks'). Steep-sided domes or 'pancake domes', larger than 20 km in diameter, were included with the small volcanic domes. For the purposes of this study, only volcanic edifices less than 20 km in diameter are discussed. This forms a convenient cutoff since most of the steep-sided domes ('pancake domes') and scalloped margin domes ('ticks') are 20 to 100 km in diameter, are much less numerous globally than are the smaller diameter volcanic edifices (2 to 3 orders of magnitude lower in total global number), and do not commonly occur in large clusters or fields of large numbers of edifices. THE LOS ALAMOS NEUTRON SPECTROMETER FOR THE LUNAR SCOUT-1 MISSION Abstract Only c35
George Auchampaugh, Bruce Barraclough, Roger Byrd, Darrell Drake, William Feldman, Calvin Moss, and Robert Reedy *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 49-50 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

We review the current status of the Los Alamos program to develop a neutron spectrometer for the Lunar Scout-1 mission, which is the first of two such missions to obtain global compositional, gravity, topography, and image maps of the lunar surface during nominal one-year missions. The neutron spectrometer will measure fast and slow (epithermal and thermal) neutrons in the ranges of 0.5 MeV to 25 MeV and 0.01 eV to more than 1 keV, respectively. The neutron spectrometer will consist of two independent instruments, a fast-neutron one, and a thermal and epithermal one. The measured neutron fluxes are very sensitive to hydrogen in the top meter of the lunar surface and provide additional information about lunar composition. Derived from text

VAPORIZATION BY SHOCK LOADING OF ALBITE, JADEITE, AND PYREX GLASS: EXPERIMENTAL STUDY Abstract Only c27

D. D. Badjukov and T. L. Petrova (Institute of Lithosphere, Moscow, Russia.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 51-52 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Produced by shock experiments impact melts of albite, jadeite, and Pyrex glass demonstrate a loss of both Na and Al relative to Si, which can be due to selective vaporization. It is suggested that the high volatility of Al is related to volatility of a Na-Al compound of proposed $NaAlO_2$ composition. The similar loss of Al and Na seems to be possible during tektite-forming processes. A degree of selective vaporization and modification of a melt chemical composition during impact processes is still poorly understood. The selective vaporization of some elements has been shown by shock experiments. The vaporization and condensation processes can take place in the lunar regolith. On this basis, there are hypotheses explaining differentiation of planetary bodies through the impact vaporization. On the other hand, studies of tektites, impact glasses, and lunar soils show that bulk compositions of impact melts are not modified significantly. In order to estimate degree of the vaporization during shock fusion, chemical compositions of experimentally produced impact melts were studied. We chose Al-containing compositions, because a high volatilization of Al during unequlibrated evaporization had been demonstrated. Derived from text

SHOCK TRANSFORMATIONS IN QUARTZITE Abstract Only c27

D. D. Badjukov, E. A. Koslov (Institute of Technical Physics, Chelyabinsk, Russia.), Yu. N. Zhugin (Institute of Technical Physics, Chelyabinsk, Russia.), and E. V. Abakshin (Institute of Technical Physics, Chelyabinsk, Russia.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 53-54 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

We report results of studies of experimental shock metamorphism in a quartzite sample. Shock pressure increases in the experiment from a rim to a center of the bowl-shaped sample due to a design of a recovery assembly. The section along an equatorial plane shows a progressive development of shock metamorphism. On the basis of observations, it is proposed that diaplectic glass can be a product of quenching a melt. RECONSTRUCTION OF THE DYNAMICS OF THE 1800-1801 HUALALAI ERUPTION: IMPLICATIONS FOR PLANETARY LAVA FLOWS Abstract Only c46

Stephen Baloga and Paul Spudis (Lunar and Planetary Inst., Houston, TX.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 55-56 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

The 1800-1801 eruption of alkalic basalt from the Hualalai volcano, Hawaii provides a unique opportunity for investigating the dynamics of lava flow emplacement with eruption rates and compositions comparable to those that have been suggested for planetary eruptions. Field observations suggest new considerations must be used to reconstruct the emplacement of these lava flows. These observations are: (1) the flow traversed the 15 km from the vent to the sea so rapidly that no significant crust formed and an observation of the eruption reported that the flow reach the sea from the vent in approximately 1 hour; (2) the drainage of beds of xenolith nodules indicates a highly fluid, low viscosity lava; (3) overspills and other morphologic evidence for a very low viscosity host fluid; (4) no significant longitudinal increase in flow thickness that might be associated with an increase in the rheological properties of the lava; and (5) the relatively large size of channels associated with the flow, up to 80 meters across and several km long. Models for many geologic mass movements and fast moving fluids with various loadings and suspensions are discussed. Derived from text

HORIZONTAL STRESSES INDUCED BY VERTICAL PROCESSES IN PLANETARY LITHOSPHERES Abstract Only c46

W. B. Banerdt *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 57-58 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Understanding the state of stress in the elastic lithosphere is of fundamental importance for planetary geophysics, as it is the link between the observed geologic structures on the surface and the processes which form and modify these structures. As such, it can provide valuable constraints for the difficult problem of determining interior structure and processes. On the Earth, most large scale, organized deformation can be related to lateral tectonics associated with plate dynamics; however, the tectonics on many extraterrestrial bodies (such as the Moon, Mars, and most of the outer-planet satellites) appears to be primarily vertical in nature, and the horizontal stresses induced by vertical motions and loads are expected to dominate the deformation of their lithospheres. The largest stress contributions from vertical loading come from the flexure of the lithosphere, which induces both bending moments and membrane stresses. We are concerned here only with nonflexural changes in the state of stress induced by processes such as sedimentary and volcanic deposition, erosional denudation, and changes in the thermal gradient that induce uplift or subsidence. This analysis is important both for evaluating stresses for specific regions in which the vertical stress history can be estimated, as well as for applying the proper loading conditions to global stress models. It is also of interest for providing a reference state of stress for interpreting stress measurements in the crust of the Earth. Derived from text

INCREASED DEPTH-DIAMETER RATIOS IN THE MEDUSAE FOSSAE FORMATION DEPOSITS OF MARS Abstract Only

N. G. Barlow *In its* Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 61-62 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Depth to diameter ratios for fresh impact craters on Mars are commonly cited as approximately 0.2 for simple craters and 0.1 for complex craters. Recent computation of depth-diameter ratios in the Amazonis-Memnonia region of Mars indicates that craters within the Medusae Fossae Formation deposits found in this region display greater depth-diameter ratios than expected for both simple and complex craters. Photoclinometric and shadow length techniques have been used to obtain depths of craters within the Amazonis-Memnonia region. The 37 craters in the 2 to 29 km diameter range and displaying fresh impact morphologies were identified in the area of study. This region includes the Amazonian aged upper and middle members of the Medusae Fossae Formation and Noachian aged cratered and hilly units. The Medusae Fossae Formation is characterized by extensive, flat to gently undulating deposits of controversial origin. These deposits appear to vary from friable to indurated. Early analysis of crater degradation in the Medusae Fossae region suggested that simple craters excavated to greater depths than expected based on the general depth-diameter relationships derived for Mars. However, too few craters were available in the initial analysis to estimate the actual depth-diameter ratios within this region. Although the analysis is continuing, we are now beginning to see a convergence towards specific values for the depth-diameter ratio depending on geologic unit. Derived from text

BEHAVIOR OF VORTICES GENERATED BY AN ADVANCING EJECTA CURTAIN IN THEORY, IN THE LABORATORY, AND ON MARS Abstract Only c34

O. S. Barnouin and P. H. Schultz *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 63-64

(For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Several papers assess the interaction between an atmosphere and advancing ejecta to assess possible atmospheric processes affecting ejecta emplacement. Ejecta travel through an atmosphere in two modes: larger ejecta blocks follow ballistic trajectories unhindered by the atmosphere; finer ejecta are entrained in a turbulent basal cloud, which develops as the advancing ejecta curtain generates strong atmospheric winds. Laboratory experiments reveal that this cloud of fine ejecta produce ramparts, flow lobes, or radial scouring that superposes larger ballistic ejecta emplaced earlier. Martian, Venusian, and terrestrial ejecta facies can be interpreted in terms of processes observed in the laboratory with appropriate first-order corrections for scaling. A continuum model of the atmospheric flow around an advancing inclined plate simulated and reproduced some of the complex flow patterns observed in front and at the top of the curtain. Here we consider improvements to the model to compare quantitatively the approximate position of ejecta deposition (i.e., run-out distance) with laboratory experiments and Martian ejecta facies. MINERALOGY OF CHONDRITIC INTERPLANETARY DUST PARTICLE IMPACT RESIDUES FROM LDEF Abstract Only **c25**
R. A. Barrett, M. E. Zolensky (National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, TX.), and R. Bernhard *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 65-66 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

A detailed structural and compositional analysis of several impactor residues was performed utilizing transmission electron microscopy, energy dispersive spectroscopy, and electron diffraction. Residues from the interior of several craters in gold surfaces were removed with a tungsten needle, mounted in EMBED-812 epoxy, and ultramicrotomed. The presence in these residues of equilibrated ferromagnesian minerals, recrystallization textures, glass, and melted metal and sulfide bodies decorating grain boundaries is indicative of varying degrees of shock metamorphism in all impact residues we have characterized. ESTIMATION OF AGE OF DALI-GANIS RIFTING AND ASSOCIATED VOLCANIC ACTIVITY, VENUS Abstract Only
A. T. Basilevsky (Academy of Sciences, USSR, Moscow.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 67-68 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

This paper deals with the estimation of age for the Dali and Ganis Chasma rift zones and their associated volcanism based on photogeologic analysis of stratigraphic relations of rift-associated features with impact craters which have associated features indicative of their age. The features are radar-dark and parabolic, and they are believed to be mantles of debris derived from fallout of the craters' ejecta. They are thought to be among the youngest features on the Venusian surface, so their 'parent' craters must also be very young, evidently among the youngest 10 percent of Venus' crater population. Dali Chasma and Ganis Chasma are a part of a system of rift zones contained within eastern Aphrodite and Atla Regio which is a significant component of Venus tectonics. The rifts of this system are fracture belts which dissect typical Venusian plains with rare islands of tessera terrain. The rift zone system consists of several segments following each other (Diane, Dali, Ganis) and forming the major rift zone line, about 10,000 km long, which has junctions with several other rift zones, including Parga Chasma Rift. The junctions are usually locations of rift-associated volcanism in the form of volcanic edifices (Maat and Ozza Montes) or plain-forming flows flooding some areas within the rift zones and the adjacent plains. INTERPRETATION OF LUNAR AND PLANETARY ELECTROMAGNETIC SCATTERING USING THE FULL WAVE SOLUTIONS Abstract Only
E. Bahar and M. Haugland *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 73-74 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Bistatic radar experiments carried out during the Apollo 14, 15, and 16 missions provide a very useful data set with which to compare theoretical models and experimental data. Vesecky, et al. report that their model for near grazing angles compares favorably with experimental data. However, for angles of incidence around 80 degrees, all the analytical models considered by Vesecky, et al. predict values for the quasi-specular cross sections that are about half the corresponding values taken from the Apollo 16 data. In this work, questions raised by this discrepancy between the reported analytical and experimental results are addressed. The unified full wave solutions are shown to be in good agreement with the bistatic radar taken during Apollo 14 and 16 missions. Using the full wave approach, the quasi-specular contributions to the scattered field from the large scale surface roughness as well as the diffuse Bragg-like scattering from the small scale surface roughness are accounted for in a unified self-consistent manner. Since the full wave computer codes for the scattering cross sections contain ground truth data only, it is shown how it can be reliably used to predict the rough surface parameters of planets based on the measured data. APOLLO 16 CORE 60013/14 AS A PRODUCT OF PATH 1 AND PATH 2 REGOLITH EVOLUTION PROCESSES Abstract Only
A. Basu, K. McBride (Lockheed Engineering and Sciences Co., Houston, TX.), S. J. Wentworth (Lockheed Engineering and Sciences Co., Houston, TX.), and D. S. McKay (National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, TX.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 75-76 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

We have made a petrographic study of 12 samples along the 62 cm profile of Apollo 16 core 60013/14 taken at Station 10 near the lunar module. The basic core description and maturity variations have been discussed earlier. This core is important because it enables a stratigraphic comparison with nearby cores 60001-7 and 60009/10. These cores form a triangle with sides 35-40 m. FMR data show a maturity-match between 60009/10 and 60013/14. Unfortunately, segments of the core 60001-7 are too disturbed for any cm scale comparison. We present new data on the grain size distribution and the modal petrography for six samples from six levels of 60013 using the same approach and rationale used for 60014. We have combined the new data with our previous data on 60014 to plot the variations of grain size distributions and grain type abundances, in the 500-1000 m and 90-150 micrometers size fractions, with depth. Agglutinate abundances match the I sub s/FeO profile and both show a significant break at a depth of about 45 cm, with lower maturity material below that point. Grain size distributions show that for all analyzed samples, the mean grain size is below 90 micrometers. The two lowest samples are somewhat more coarse-grained than the rest of the core. The break at about 45 cm is the most prominent feature of the core and was described during the initial dissection as a pronounced change in color from dark to light. It now seems clear that this break is primarily one of maturity rather than of bulk chemical composition. Derived from text

NITROGEN AND NOBLE GASES IN A GLASS SAMPLE FROM LEW88516 Abstract Only c25
R. H. Becker and R. O. Pepin *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 77-78
(For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The Antarctic meteorite LEW88516 has been classified as a member of the SNC group of meteorites, specifically a shergottite. It is reported to be remarkably similar in mineralogy, petrogenesis and chemistry to the previously known ALH77005 shergottite, with both being compositionally distinct from other shergottites. LEW88516 shows pervasive shock features and has been found to contain glass veins attributable to a shock origin. In an effort to determine whether the glass in LEW88516 contains any of the isotopically-heavy trapped nitrogen component observed in EETA 79001 glass, as well as the related high-Ar-40/Ar-36 and high-Xe-129/Xe-132 components, we undertook an analysis of an 11.9 mg glass sample (LEW88516,4) provided to us by H. Y. McSween, Jr. as part of a consortium study of this meteorite. Nitrogen and noble gases were extracted from LEW88516,4 in a series of combustion steps at increasing temperatures followed by a final pyrolysis. Initial steps at 550 C were intended to remove any surface-sited nitrogen-containing contaminants, while the 700 C step was expected to show the onset of release of a trapped argon component, based on our previous data for EETA 79001. It was hoped that the bulk of any trapped gas release would be concentrated in one of two steps at 1100 C and approximately 1400 C, maximizing our analytical sensitivity. Results of the analysis are shown. Except for He and Ne, data obtained for the 550 C steps will be omitted from further consideration on the assumption that they represent terrestrial contamination. THE STABILITY OF HIBONITE AND OTHER ALUMINOUS PHASES IN SILICATE MELTS: IMPLICATIONS FOR THE ORIGIN OF HIBONITE-BEARING INCLUSIONS Abstract Only c25
J. R. Beckett and E. Stolper *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 79-80
(For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Phase fields in which hibonite (Hib) and silicate melt coexist with spinel (Sp), CaAl4O7 (CA2), gehlenitic melilite (Mel), anorthite (An), or corundum (Cor) in the system CaO-MgO-Al2O3-SiO2-TiO2 (CMAST) were determined and activity models developed for Mel and Hib solid solutions. Experimentally determined partition coefficients for Ti between Hib and coexisting melt, D sub t, vary from 0.8 to 2.1 and generally decrease with increasing TiO2 content in the liquid (L). Based on Ti partioning between Hib and melt, bulk inclusion compositions and Hib-saturated liquid use phase diagrams, the Hib in Fluffy Type A inclusions (FTA's) from Allende and at least some of the Hib from Hib-rich inclusions is relict; much of the Hib from Hib-glass spherules probably crystallized from a melt under nonequilibrium conditions. Bulk compositions for all of these Ca-Al-rich inclusions (CAI's) are consistent with an origin as Mel + Hib + Sp + perovskite (Pv) proto-inclusions in which Mel was partially altered. In some cases, the proto-inclusion was partially or completely melted with vaporization occurring over a period of time sufficient to remove any Na introduced by the alteration process but frequently insufficient to dissolve all of the original hibonite. If equilibration temperatures based on Hib-bearing CAI's reflect condensation in a cooling gas of solar composition, then Hib + Cor condensed at approximately 1260 C (referenced to 10 exp -3 atm) and Hib + Sp + Mel at approximately 1215 +/- 10 C. Simple thermochemical models for the substitution of trace elements into the Ca-site of meteoritic Hib suggest that virtually all Eu is divalent in early condensate Hibs but that Eu(2+)/Eu(3+) decreases by a factor of 20 or more during the course of condensation, primarily because the ratio is proportional to the partial pressure of Al, which decreases dramatically as aluminous phases condense. The relative sizes of Eu and Yb anomalies in meteoritic Hibs and CAI's may be influenced by this effect. Derived from text

A COMPARISON OF TELESCOPIC AND PHOBOS-2 ISM SPECTRA OF MARS IN THE SHORT-WAVE NEAR-INFRARED (0.76-1.02 MICRONS) Abstract Only c89
James F. Bell, III and John F. Mustard (Brown Univ., Providence, RI.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 81-82 Sponsored by NASA. Washington (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Recent analyses of near-IR (0.76-3.16 microns) Mars surface reflectance spectra obtained by the Phobos-2 ISM instrument during early 1989 have revealed the presence of substantial variability in surface spectral properties. Strong absorption features seen in the 0.85-1.05 micron region are up to 10-15 percent deep relative to the local continuum and have been interpreted as evidence of Fe(2+) and Fe(3+) bearing minerals (pyroxenes and iron oxides, respectively). Though these observed band depths are comparable to those seen in laboratory reflectance spectra, they are up to three times larger than most previously reported band depths for Mars spectra at these wavelengths. Six regions of variable albedo and geologic setting were identified where ISM and 1988 opposition telescopic coverage either overlapped physically or sampled the same surface geologic unit. The areal sizes and positions of the regions measured telescopically were compiled by Bell et al. ISM pixels falling within these spots were averaged to produce a spatially convolved spectrum that simulates what would have been seen telescopically. To facilitate comparisons of absorption band positions and relative strengths, the convolved ISM data and the 1988 telescopic spectra were scaled to unity at 0.81 microns and are presented. The data have also been convolved to equivalent band pass normalized reflectances in the region of spectral overlap. A scatter diagram of telescopic vs. ISM reflectances is shown. The results from the investigation are discussed. Derived from text

AN OBSERVATIONAL SEARCH FOR CO2 ICE CLOUDS ON MARS Abstract Only
James F. Bell, III, Wendy M. Calvin (Geological Survey, Flagstaff, AZ.), James B. Pollack, and David Crisp (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 83-84 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

CO2 ice clouds were first directly identified on Mars by the Mariner 6 and 7 infrared spectrometer limb scans. These observations provided support for early theoretical modeling efforts of CO2 condensation. Mariner 9 IRIS temperature profiles of north polar hood clouds were interpreted as indicating that these clouds were composed of H2O ice at lower latitudes and CO2 ice at higher latitudes. The role of CO2 condensation on Mars has recently received increased attention because (1) Kasting's model results indicated that CO2 cloud condensation limits the magnitude of the proposed early Mars CO2/H2O greenhouse, and (2) Pollack el al.'s GCM results indicated that the formation of CO2 ice clouds is favorable at all polar latitudes during the fall and winter seasons. These latter authors have shown that CO2 clouds play an important role in the polar energy balance, as the amount of CO2 contained in the polar caps is constrained by a balance between latent heat release, heat advected from lower latitudes, and thermal emission to space. The polar hood clouds reduce the amount of CO2 condensation on the polar caps because they reduce the net emission to space. There have been many extensive laboratory spectroscopic studies of H2O and CO2 ices and frosts. In this study, we use results from these and other sources to search for the occurrence of diagnostic CO2 (and H2O) ice and/or frost absorption features in ground based near-infrared imaging spectroscopic data of Mars. Our primary goals are (1) to try to confirm the previous direct observations of CO2 clouds on Mars; (2) to determine the spatial extent, temporal variability, and composition (H2O/CO2 ratio) of any clouds detected; and (3) through radiative transfer modeling, to try to determine the mean particle size and optical depth of polar hood clouds, thus, assessing their role in the polar heat budget.

CHANGES IN HAWAIIAN PALAGONITE FE MINERALOGY ASSOCIATED WITH THERMAL ALTERATION: IMPLICATIONS FOR MARS Abstract Only **c46**

James F. Bell, III, Richard V. Morris (National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, TX.), and John B. Adams (Washington Univ., Seattle.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 85-86 Sponsored by NASA. Washington (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

We have studied six Hawaiian palagonitic tephra samples (PH-1 through PH-6) from a site where a Mauna Loa lava flow has partially embayed a Mauna Kea cinder cone Tephra samples that were not affected by the lava flow (PH-5, PH-6) consist of partially palagonitized coarse-grained glassy Hawaiitic particles whose iron mineralogy is dominated by nanophase ferric oxide (np-Ox) and olivine. Samples closest to the lava flow (PH-1 through PH-4) have been strongly altered and their iron mineralogy is dominated by np-Ox, magnetite, and hematite. This suite of samples has many spectral similarities to Martian bright regions; thus, this localized thermal alteration event may be an analog to similar processes on Mars that lead to the production of small amounts of crystalline ferric oxides within a poorly-crystalline or amorphous palagonitic matrix.

PETROGRAPHY AND PRELIMINARY INTERPRETATIONS OF THE CRYSTALLINE BRECCIAS FROM THE MANSON M-1 CORE Abstract Only **c46**

M. S. Bell, M. K. Reagan, R. R. Anderson, and C. T. Foster, Jr. *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 87-88 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

The M-1 core was drilled on the eastern edge of the central uplift within the Manson Impact Structure in Iowa. The lower 107.9 m of the core consists of crystalline breccias. Twelve intervals of thin sections from this core have been studied for preliminary discussion. The breccias are divided into three units by matrix size and abundance. Unit 1 is characterized by a high volume fraction of matrix, and a decreasing proportion of matrix with depth. This matrix is nearly isotropic and consists of grains less than 0.005 to less than 0.02 mm in length. The matrix between 112 and 146 meters depth consists of a crystalline intergrowth of felsic and opaque minerals with or without chlorite. This was the hottest section of the core after impact, and may have undergone high temperature metamorphic recrystallization. Unit 2 is transitional between units 1 and 3, and is delineated by a rapid increase in grain size to .01-.04 mm and a decrease in matrix abundance to 10 percent. Unit 3 has a coarse, often porous matrix, whose abundance changes from about 10 percent at the top to about 2 percent at the base. Grain sizes range from 0.01-0.1 mm over this interval and coarsen with depth. Changes in the character of the matrix as well as the changes in clast lithology and abundance outlined below suggest that unit 3 is in-situ brecciated basement with injected melt and shale fragments; unit 1 is a crater veneer deposit consisting of transported basement materials and unit 2 is a mixed zone between units 1 and 3. ORBITAL SIMULATIONS OF SATELLITE ESCAPE/CAPTURE AND THE ORIGIN OF SATELLITES SUCH AS TRITON Abstract Only **c90**

Lance A. M. Benner and William B. McKinnon *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 89-90 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

We investigate satellite escape/capture in the context of the restricted, circular three body problem as applied to the Sun, Neptune, and Triton. We have computed a large number of coplanar prograde and retrograde orbital simulations over a range of initial distances and velocities. The satellite starts at superior conjunction within approximately 2 Hill radii of Neptune and has a velocity orthogonal to the Sun-planet line. Orbits with these initial conditions can be reflected with respect to time, so an escape is simply the reverse of a capture. We numerically integrate the equations of motion to compute the satellite's position until it escapes, collides with Neptune, or after 100 planetary years fails to escape, when computations cease. The initial distance x and velocity v in the restricted problem uniquely define the Jacobi constant C, a conserved energy-like quantity. Plots of the simulation outcomes in the prograde and retrograde C, x phase spaces reveal distinct zones in which temporary satellites approach the planet closely enough that permanent capture can be effected by gas drag with a protoplanetary nebula or by collision with a pre-existing satellite. Single and double close-flybys constitute the most common possible capture orbits. Long term multiple flyby orbits occur near the stability limits between bound and unbound orbits, and are more common among retrograde captures. Derived from text

THE GREAT 8 MA EVENT AND THE STRUCTURE OF THE H-CHONDRITE PARENT BODY Abstract Only **c90**

P. H. Benoit and D. W. G. Sears *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 91-92 (For primary document see N94-12015 01-91)
(Grant NAG9-81)

Avail: CASI HC A01/MF A06

The H-chondrites have been the subject of several recent controversies, including the question of whether Antarctic and non-Antarctic meteorites are or are not the same and whether there or is not evidence for stratigraphic layering in the original parent body. We have identified two distinct groups of H5 chondrites in the Antarctic collection. One group has induced thermoluminescence (TL) peak temperatures less than 190 C and metallographic cooling rates between S to 50 K/Myr, similar to modern falls. It also has a variety of cosmic ray exposure ages, many being greater than 107 years. The other group has TL peak temperatures greater than 190 C, metallographic cooling rates of 100 K/Myr and cosmic ray exposure ages of 8 Ma. The members of this group were generals smaller than those of the greater than 190 C group (including the mode falls) during cosmic ray exposure. Detailed study of the cosmogenic nuclide concentrations of these groups indicates that they are not solely the result of pairing of a few unusual meteorites. It is likely that the greater than 190 C group was an important part of the H-chondrite flux about 1 million years ago, but has since decreased in importance relative to the less than 190 C group. In a previous work, we discussed several possible origins for the greater than 190 C group, including multiple H-chondrite parent bodies, unusual parent body structure, and creation during the 8 Ma event. In this paper, we present new data for H4 chondrites in light of these ideas.

METEORITES FROM RECENT AMOR-TYPE ORBITS Abstract Only **c90**

P. H. Benoit and D. W. G. Sears *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 93-94 (For primary document see N94-12015 01-91)
(Grant NAG9-81)

Avail: CASI HC A01/MF A06

We report here the discovery of a recent meteorite shower in Antarctica, the members of which have very high natural thermoluminescence levels. It is apparent from these data that the shower has been on Earth only a short time (approximately 1000 years) and the meteorite probably came to

Earth through rapid (less than 10 exp 5 years) evolution from an orbit with perihelion greater than 1.1 AU, similar to Amor asteroids. Only a very small number of meteorites, including a few modern falls, appear to have had similar orbital histories. Derived from text

Avail: CASI HC A01/MF A06

Meteorites and lunar samples have been irradiated by high energy cosmic rays, typically for millions of years. In addition to producing isotopic changes, the irradiation creates ionization which may be recorded in the form of stored thermoluminescence (TL) in certain minerals, the most important of which is feldspar. One aspect of interpreting the TL of these samples is the effect of 'shielding' or depth control, which is particularly important for meteorites, since they have lost an unknown amount of mass during atmospheric entry. Here we report theoretical calculations which we compare with samples from lunar cores for which we have excellent stratigraphic control. We then discuss the implications for these results for the TL of meteorites, which have a different irradiation geometry. We find that, in general, calculated profiles are similar to those observed in lunar samples and meteorites. Additional effects, such as orbital (thermal) history and terrestrial age must also be considered in the case of meteorites. Author

METALLOGRAPHIC COOLING RATES OF L-GROUP ORDINARY CHONDRITES Abstract Only c90
Marvin E. Bennett and Harry Y. McSween, Jr. *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 97-98 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Shock metamorphism appears to be a ubiquitous feature in L-group ordinary chondrites. Brecciation and heterogeneous melting obscure much of the early history of this meteorite group and have caused confusion as to whether L chondrites have undergone thermal metamorphism within onion-shell or rubble-pile parent bodies. Employing the most recent shock criteria, we have examined 55 Antarctic and 24 non-Antarctic L chondrites in order to identify those which have been least affected by post-accretional shock. Six low-shock samples (those with shock grade less than S4) of petrographic types L3-L5 were selected from both populations and metallographic cooling rates were obtained following the technique of Willis and Goldstein. All non-Antarctic L6 chondrites inspected were too heavily shocked to be included in this group. However, 4 shocked L6 chondrites were analyzed in order to determine what effects shock may impose on metallographic cooling rates. Metallographic cooling rates were derived by analyzing the cores of taenite grains and then measuring the distance to the nearest grain edge. Taenites were identified using backscatter imaging on a Cameca SX-50 electron microprobe. Using backscatter we were able to locate homogeneous, rust-free, nearly spherical grains. M-shaped profiles taken from grain traverses were also used to help locate the central portions of selected grains. All points which contained phosphorus above detection limits were discarded. Plots of cooling-rate data are summarized and data from the high-shock samples are presented. The lack of coherency of cooling rates for individual samples is indicative of heterogeneous cooling following shock. The data confirms the statement expressed by numerous workers that extreme care must be taken when selecting samples of L chondrites for cooling-rate studies. Data for the 6 non-Antarctic low-shock samples are also presented. The samples display a general trend in cooling rates. The lowest metamorphic grade yielded the slowest cooling rates and an increase in grade follows an increase in cooling rate. This is the opposite relationship to that predicted by the onion-shell model. Derived from text

EXPLICIT 3D CONTINUUM FRACTURE MODELING WITH SMOOTH PARTICLE HYDRODYNAMICS Abstract Only c90
W. Benz and E. Asphaug *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 99-100
(For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Impact phenomena shaped our solar system. As usual for most solar system processes, the scales are far different than we can address directly in the laboratory. Impact velocities are often much higher than we can achieve, sizes are often vastly larger, and most impacts take place in an environment where the only gravitational force is the mutual pull of the impactors. The Smooth Particle Hydrodynamics (SPH) technique has been applied in the past to the simulations of giant impacts. In these simulations, the colliding objects were so massive (at least a sizeable fraction of the Earth's mass) that material strength was negligible compared to gravity. This assumption can no longer be made when the bodies are much smaller. To this end, we have developed a 3D SPH code that includes a strength model to which we have added a von Mises yielding relation for stresses beyond the Hugoniot Elastic Limit. At the lower stresses associated with brittle failure, we use a rate-dependent strength based on the nucleation of incipient flaws whose number density is given by a Weibull distribution. Following Grady and Kipp and Melosh et al., we introduce a state variable D ('damage'), 0 less than D less than 1, which expresses the local reduction in strength due to crack growth under tensile loading. Unfortunately for the hydrodynamics, Grady and Kipp's model predicts which fragments are the most probable ones and not the ones that are really formed. This means, for example, that if a given laboratory experiment is modeled, the fragment distribution obtained from the Grady-Kipp theory would be equivalent to a ensemble average over many realizations of the experiment. On the other hand, the hydrodynamics itself is explicit and evolves not an ensemble average but very specific fragments. Hence, there is a clear incompatibility with the deterministic nature of the hydrodynamics equations and the statistical approach of the Grady-Kipp dynamical fracture model. We remedy these shortcomings by making the incipient flaw distribution explicit, i.e., particles carry activation strains which are distributed at random with a probability of occurrence given by the Weibull distribution. If the local principal axis strain exceeds this limit, damage starts to grow. By growing explicit cracks together with statistical cracks (damage) at the sub-particle scale, we ensure that material strength and fragmentation is independent of model resolution. We tested our scheme by simulating laboratory impact experiments on basalt spheres. Derived from text

COMPOSITION AND MODAL FREQUENCIES OF HYPERVELOCITY PARTICLES LESS THAN 1 MILLIMETER IN DIAMETER IN LOW-EARTH ORBIT Abstract Only c90
R. P. Bernhard, T. H. See, and F. Hoerz (National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, TX.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 101-102 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

We have continued to systematically analyze the projectile residues associated with hypervelocity impact features on the surfaces of the 'Chemistry of Micrometeoroid Experiment' (CME) that was in low-Earth orbit (LEO) for 5.7 years aboard the Long Duration Exposure Facility (LDEF). Last year we reported on the systematic analysis, via SEM-EDX methods, of all craters greater than 20 microns in diameter on the collectors from LDEF's trailing edge and approximately 200 craters greater than 75 microns in diameter from the aluminum 1100 substrates from the forward-facing surfaces. This latter group represents less than 20 percent of all craters on the A11 collectors, because the particle flux is substantially higher for the forward-facing orientations relative to the trailing-edge surfaces. To date, we have analyzed some 600 craters on the A11 aluminum collectors, yet this report summarizes only 400 features, because not all of the results have been completely reduced and entered into our database. THERMAL STUDIES OF MARTIAN CHANNELS AND VALLEYS USING TERMOSKAN DATA Abstract Only
B. H. Betts and B. C. Murray *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 103-104

(For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The Termoskan instrument on board the Phobos '88 spacecraft acquired the highest spatial resolution thermal data ever obtained for Mars. Included in the thermal images are 2 km per pixel observations of 4 major channel and valley systems: Shalbatana Vallis; Simud Vallis, Hydraotes Chaos, and the associated outflow channel connecting it with the eastern end of Vallis Marineris; Al-Qahira Vallis; and Ma'adim Vallis. Simultaneous broad band visible channel data were obtained for all but Ma'adim Vallis. We find that all 4 valley systems have higher inertias than their surroundings, consistent with previous thermal studies of Martian channels. We conclude that the higher inertia is likely due to some intrinsic difference associated with the channel floors, rather than due only to dark aeolian deposits as suggested by some previous studies. Our conclusion is based largely upon the localized nature of the dark deposits in contrast with the thermal homogeneity of the channel floors. Thus, these channels and valleys show an uncommon (for Mars) connection between morphology and inertia. Derived from text

SPECTRAL ANALYSIS OF THE GRAVITY AND TOPOGRAPHY OF MARS Abstract Only

Bruce G. Bills, Herbert V. Frey, Walter S. Kiefer, R. Steven Nerem, and Maria T. Zuber (Johns Hopkins Univ., Baltimore, MD.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 105-106 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

New spherical harmonic models of the gravity and topography of Mars place important constraints on the structure and dynamics of the interior. The gravity and topography models are significantly phase coherent for harmonic degrees n less than 30 (wavelengths greater than 700 km). Loss of coherence below that wavelength is presumably due to inadequacies of the models, rather than a change in behavior of the planet. The gravity/topography admittance reveals two very different spectral domains: for n greater than 4, a simple Airy compensation model, with mean depth of 100 km, faithfully represents the observed pattern; for degrees 2 and 3, the effective compensation depths are 1400 and 550 km, respectively, strongly arguing for dynamic compensation at those wavelengths. The gravity model has been derived from a reanalysis of the tracking data for Mariner 9 and the Viking Orbiters, The topography model was derived by harmonic analysis of the USGS digital elevation model of Mars. Before comparing gravity and topography for internal structure inferences, we must ensure that both are consistently referenced to a hydrostatic datum. For the gravity, this involves removal of hydrostatic components of the even degree zonal coefficients. For the topography, it involves adding the degree 4 equipotential reference surface, to get spherically referenced values, and then subtracting the full degree 50 equipotential. Variance spectra and phase coherence of orthometric heights and gravity anomalies are addressed. Derived from text

GLOBAL ORGANIZATION OF TECTONIC DEFORMATION ON VENUS Abstract Only

Frank Bilotti, Chris Connors, and John Suppe *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 107-108 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The geographic organization of surface deformation on Venus as on Earth is a key to understanding the global tectonic system. To date we have mapped the distribution of three unambiguous tectonic land forms on Venus: (1) linear foldbelts analogous to those at plate margins of the Earth; (2) linear rift zones, analogous to continental rifts on the Earth; and (3) distributed plains deformation in the form of wrinkle ridges and extensional faults and fractures. The linear foldbelts are the dominant structural style in the Northern Hemisphere; ninety percent of the planet's foldbelts lie above the equator. In contrast, compressive deformation in the Southern Hemisphere is dominated by two large, sweeping patterns of wrinkle ridges. The two hemispheres are divided by an equatorial region that is largely covered by rift zones and several large tessera blocks. A tectonic model of generally poleward convergence of the Northern Hemisphere explains the distribution of foldbelts and rift zones. In our model, a northern hemispherical plate (or system of plates) moves poleward and deforms along discrete, predominately longitudinal bands. We recognize four types of foldbelts based on their relationships to other large-scale tectonic features on Venus. There are foldbelts that lie within the low plains, foldbelts associated with coronae, novae and chasmata, foldbelts that lie at the margins of poly-deformed tessera plateaus, and the folded mountain belts around Lakshmi Planum. We see a geometric increase in the area of fold belts when normalized to percent area at a given latitude. This increase is consistent with our model of poleward convergence. Also, the orientations of most foldbelts are either approximately north-south or parallel to lines of latitude in the northern hemisphere. This observation is also consistent with the model in that the longitudinal bands are the result of the decreasing area of the sphere as the plate moves poleward and the latitudinal belts are the direct result of poleward compression. The trends of wrinkle ridges have been mapped over the planet and several large, sweeping patterns evidently reflect long-wavelength topography. Using wrinkle ridges as paleostress indicators, we have developed local and regional stress trajectory maps. Derived from text

VENUS' CENTER OF MASS - CENTER OF FIGURE DISPLACEMENT AND IMPLICATIONS Abstract Only

D. L. Bindschadler and G. Schubert *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 109-110 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Earth, Moon, Mars, and Venus all have centers of mass (C.M.) that are displaced from their centers of figure (C.F.) by amounts which range from 340 meters (Venus) to 2.5 km (Mars). These offsets have all been calculated from the first degree terms in spherical harmonic expansions of topography. We describe an alternate method for calculating C.M. - C.F. offsets directly from a global topographic data set and apply it to Venus. Using Magellan altimetry, we find that Venus' C.F. is displaced approximately 280 meters from its C.M. in the direction of Western Aphrodite Terra (4.4 deg S, 135.8 deg E). We investigate several simple models for this offset and find that it is most consistent with thickened crust in Ovda and Thetis Regiones (which constitute most of W. Aphrodite). The location of the C.F. offset also places constraints on the degree of crustal thickening in Western Ishtar Terra and/or this highland's mode of origin. We favor a model in which offset due to thick crust in Western Ishtar Terra is balanced by an opposing offset due to cold, downwelling mantle material beneath the highland. Derived from text

THE ASTEROID-METEORITE CONNECTION: FORGING A NEW LINK TO VESTA AS THE PARENT BODY OF BASALTIC ACHONDRITE (HED) METEORITES Abstract Only c90

R. P. Binzel *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 111 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Asteroid 4 Vesta has been at the center of the debate over the identity of the howardite eucrite diogenite (HED) parent body since the early 1970s. Despite its unique (among the 500 largest asteroids) compositional match to HED meteorites, substantial dynamical difficulties in delivering fragments from Vesta to the Earth have precluded any conclusive HED parent body link. These dynamical difficulties arise because Vesta's orbital location is far from known resonances. Consequently, it has been argued as dynamically improbable that meteoroid-sized (1 km) fragments could be excavated from Vesta with sufficient velocities to reach the resonances. Through new astronomical observations, numerous small (4-7 km) asteroids between Vesta and the 3:1 resonance have been discovered to have eucrite and diogenite compositions. Based on similar orbital elements to Vesta, all of these new asteroids are likely large impact fragments excavated from Vesta. Their current orbits imply ejection velocities in excess of 700 m/sec. Smaller (1 km) fragments can therefore be expected to have been ejected with velocities greater than 1 km/sec, sufficient to reach the 3:1 and v6 resonances. Thus it now appears to be dynamically viable for Vesta to be linked as the HED parent body. Author (revised)

ALKALI-GRANITOIDS AS FRAGMENTS WITHIN THE ORDINARY CHONDRITE ADZHI-BOGDO: EVIDENCE FOR HIGHLY FRACTIONATED, ALKALI-GRANITIC LIQUIDS ON ASTEROIDS Abstract Only **c90**
A. Bischoff *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 113-114 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Adzhi-Bogdo is an ordinary chondrite regolith breccia (LL3-6) that fell October 30, 1949 in Gobi Altay, Mongolia. The rock consists of submm- to cm-sized fragments embedded in a fine-grained elastic matrix. The breccia contains various types of clasts, some of which must be of foreign heritage. Based on chemical compositions of olivine some components have to be classified as L-type. Components of the breccia include chondrules, impact melts (some are K-rich, similar to those found in other LL-chondrites, highly recrystalized rock fragments ('granulites'), pyroxene-rich fragments with achondritic textures, and alkali-granitoidal fragments that mainly consist of K-feldspar and quartz or tridymite. Probably, this is the first report on granitoids from asteroids. It can be ruled out that these fragments represent huge rock assemblages of the parent body like granites do on Earth. Therefore, to avoid misunderstandings, these rocks will be designated as granitoids. In one thin section four granitoids were observed. The main phases within these clasts are K-feldspar and SiO2-phases. Minor phases include albite, Cl-apatite, whitlockite, ilmenite, zircon, Ca-poor pyroxene, and an unidentified Na,Ti-bearing silicate. Based on chemical composition and on optical properties quartz appears to be the SiO2-phase in two fragments, whereas tridymite seems to occur in the other two. The calculated formula of the unknown Na,Ti-rich silicate is very close to (Na,Ca)2.7(Fe,Mg)6(Ti)1.3(Si)7(O)24. Quartz and K-feldspar can reach sizes of up to 700 microns. Thus, the fragments can be described as coarse-grained (by chondritic standards). This is especially the case considering that quartz and K-feldspar are very rare minerals in ordinary chondrites. Representative analyses of minerals from some granitoidal clasts are given. Based on the mineral compositions and the modal abundances the bulk compositions were calculated. Besides these granitoidal rocks, pyroxene-rich fragments occur that show exsolution textures that are similar to those found in eucrites. Derived from text

REFLECTANCE SPECTRA OF SULFATE-AND CARBONATE-BEARING Fe(3+)-DOPED MONTMORILLONITES AS MARS SOIL ANALOGS Abstract Only
Janice L. Bishop, Carle M. Pieters, and Roger G. Burns (Massachusetts Inst. of Tech., Cambridge.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 115-116 (For primary document see N94-12015 01-91)
(Grants NAGw-28; NAGw-2220; NAGw-748)
Avail: CASI HC A01/MF A06

Ferric smectites and ferrihydrite may be common alteration products of igneous lithologies on Mars, and experiments involving montmorillonite enriched with Fe(3+) support the likelihood of ferric smectites on Mars. Mossbauer spectroscopy has been used to identify ferrihydrite (Fe4(O,OH,H2O)12) as the primary ferric material in Fe(3+)-doped montmorillonite. Ferrihydrite is especially interesting due to its role as a precursor in the formation of hematite and goethite. Reflectance spectroscopy in the visible and infrared regions are coupled with Mossbauer spectroscopy in this study to characterize the ferric material in montmorillonites containing Fe(3+), as well as carbonates or sulfates, in the interlayer region. THE EFFECTS OF ATMOSPHERIC PRESSURE ON INFRARED REFLECTANCE SPECTRA OF MARTIAN ANALOGS Abstract Only
Janice L. Bishop, Carle M. Pieters, Stephen F. Pratt, and William Patterson *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 117-118 (For primary document see N94-12015 01-91)
(Grants NAGw-28; NAGw-748)
Avail: CASI HC A01/MF A06

The use of terrestrial samples as analogs of Mars soils are complicated by the Martian atmosphere. Spectral features due to the Martian atmosphere can be removed from telescopic spectra of Mars and ISM spectra of Mars, but this does not account for any spectral differences resulting from atmospheric pressure or any interactions between the atmosphere and the surface. We are examining the effects of atmospheric pressure on reflectance spectra of powdered samples in the laboratory. Contrary to a previous experiment with granite, no significant changes in albedo or the Christiansen feature were observed from 1 bar pressure down to a pressure of 8 micrometers Hg. However, reducing the atmospheric pressure does have a pronounced affect on the hydration features, even for samples retained in a dry environment for years. Derived from text

Avail: CASI HC A01/MF A06

Delta O-18 analyses of the Naivasha rhyolites, basalts, Menengai trachytes and the Yatta phonolite are presented together with D/H analyses of the Naivasha rhyolites. Delta O-18 results vary from 5.7 to 8.9 per mill which is within the reported range of delta O-18 analyses for continental volcanics. Closure temperatures calulated from the basalts and rhyolites show equilibration to be at magmatic temperatures. D/H values range from -40 to -148 per mill indicating that the rhyolites have undergone large scale degasssing. Derived from text

U-Th disequilibrium analyses of the Naivasha basalts show a very small (U-238/Th-230) ratios which are lower than any previously analyzed basalts. The broadly positive internal isochron trend from one sample indicates that the basalts may have source heterogeneities, this is supported by earlier work. The Naivasha complex comprises a bimodal suite of basalts and rhyolites. The basalts are divided into two stratigraphic groups each of a transitional nature. The early basalt series (EBS) which were erupted prior to the Group 1 comendites and, the late basalt series (LBS) which erupted temporally between the Broad Acres and the Ololbutot centers. The basalts represent a very small percentage of the overall eruptive volume of material at Naivasha (less than 2 percent). The analyzed samples come from four stratigraphic units in close proximity around Ndabibi, Hell's Gate and Akira areas. The earliest units occur as vesicular flows from the Ndabibi plain. These basalts are olivine-plagioclase phyric with the associated hawaiites being sparsely plagioclase phyric. An absolute age of 0.5Ma was estimated for these basalts. The next youngest basalts flows occur as younger tuft cones in the Ndabibi area and are mainly olivine-plagioclase-clinopyroxcene phyric with one purely plagioclase phyric sample. The final phase of activity at Ndabibi resulted in much younger tuft cones consisting of air fall ashes and lapilli tufts. Many of these contain resorbed plagioclase phenocrysts with sample number 120c also being clinopyroxene phyric. The isotopic evidence for the basalt formation is summarized. Derived from text

TH-230 - U-238 SERIES DISEQUILIBRIUM OF THE OLKARIA BASALTS GREGORY RIFT VALLEY, KENYA: PETROGENESIS Abstract Only **c46**
S. Black, R. Macdonald, and M. Kelly *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 123-124 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Strong mixing trends on a (Th-230/Th-232) versus Th diagram show that the basalts are mixed magmas which have undergone interaction with the crust. Instantaneous Th/U ratios are less than time integrated ones but these exceed the Th/U ratios in the MORB and OIB sources. This indicates that the mantle may have undergone some metasomatic fluxing, crustal contamination of the basalts will also enhance these ratios. Early activity on the Akira plain is represented by early basalts and hawaiites.

The early basalt samples are known to predate the earliest comendites. The most recent phase of activity is represented by another cinder cone 40-50 m high being feldspar and clinopyroxene phyric. Inclusions which occur in the comendites vary in size and distribution. The largest and most porphyritic are the trachytes (up to 40 cm) with alkali feldspar phases up to 6 mm and small pyroxenes in the ground mass. The second set of inclusions are smaller (up to 10 cm) and are largely aphyric. The distribution of the inclusions are not uniform, the Broad Acres (C5) lavas contain 2-5 percent. The size of the inclusions decrease from south to north, as does the abundance of the trachytic inclusions. The major element variations in the Naivasha basalts, hawaiites and magmatic inclusions are discussed.

Positive correlations of (U-238/Th-230) versus Th show the rhyolites to be products of partial melting. Positive correlations of U and Cl and U and F show that the U enrichment in the rhyolites is associated with the halogen contents which may be related to the minor phenocryst phase fractionation. Instantaneous Th/U ratios exceed time integrated Th/U ratios providing further evidence of the hydrous nature of the Olkaria rhyolite source. Excess (U-238/Th-230) in the subduction related rocks has been associated to the preferential incorporation of uranium in slab derived fluids, but no evaluation of the size of this flux has been made. The majority of the Naivasha samples show a (U-238/Th-230) less than 1 and plot close to the subduction related samples indicating the Naivasha rhyolites may also have been influenced by fluids during their formation. In general samples with high (U-238/Th-230) ratios reflecting recent enrichment of uranium relative to thorium have high thorium contents, thereby the high (U-238/Th-230) ratios are restricted to the most incompatible element enriched magmas and, hence, are a good indication that the rhyolites were formed by partial melting. If a fluid phase had some influence on the formation of the rhyolites then the uranium and thorium may have some correlation with F and Cl contents which can be mirrored by the peralkalinity. Plots of uranium against F and Cl contents are shown. The positive correlation indicates that the uranium enrichments are associated with the halogen contents. There seems to be a greater correlation for U against Cl than F indicating that the U may be transported preferentially as Cl complexes. Derived from text

TH-230 - U-238 SERIES DISEQUILIBRIUM OF THE OLKARIA RHYOLITES GREGORY RIFT VALLEY, KENYA: RESIDENCE TIMES Abstract Only **c46**
S. Black, R. Macdonald, and M. Kelly *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 127-128 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

U-series disequilibrium analyses have been conducted on samples from Olkaria rhyolite centers with ages being available for all but one center using both internal and whole rock isochrons. 67 percent of the rhyolites analyzed show U-Th disequilibrium, ranging from 27 percent excess thorium to 36 percent excess uranium. Internal and whole rock isochrons give crystallization/formation ages between 65 ka and 9 ka, in every case these are substantially older than the eruptive dates. The residence times of the rhyolites (U-Th age minus the eruption date) have decreased almost linearly with time, from 45 ka to 7 Ka suggesting a possible increase of activity within the system related to increased basaltic input. The long residence times are mirrored by large Rn-222 fluxes from the centers which cannot be explained by larger U contents. Derived from text

USING HIGH SPECTRAL RESOLUTION SPECTROPHOTOMETRY TO STUDY BROAD MINERAL ABSORPTION FEATURES ON MARS Abstract Only
D. L. Blaney and D. Crisp *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 129-130 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Traditionally telescopic measurements of mineralogic absorption features have been made using relatively low to moderate (R=30-300) spectral resolution. Mineralogic absorption features tend to be broad so high resolution spectroscopy (R greater than 10,000) does not provide significant additional compositional information. Low to moderate resolution spectroscopy allows an observer to obtain data over a wide wavelength range (hundreds to thousands of wavenumbers) compared to the several wavenumber intervals that are collected using high resolution spectrometers. However, spectrophotometry at high resolution has major advantages over lower resolution spectroscopy in situations that are applicable to studies of the Martian surface, i.e., at wavelengths where relatively weak surface absorption features and atmospheric gas absorption features both occur.

Sandford theoretically explored the use of solar flare track densities in interplanetary dust particles (IDP's) to distinguish whether they were of cometary or asteroidal origin. He determined that there were differences in the characteristic distributions of track densities that would occur from these two possible sources. Flynn examined the heating of IDP's on atmospheric entry and concluded that IDP's must be predominantly from asteroidal sources because these asteroidal particles would have sufficiently low velocities to survive atmospheric heating with little or no modification whereas cometary particles would ordinarily have velocities that are much higher. This paper looks at what we can learn by combining the approaches of Sandford and Flynn. Derived from text

Near-IR reflectance spectra (0.6-2.5 microns) and CCD images in the extended visible range (0.4-1.0 microns) obtained with Earth-based telescopes have been used to investigate the composition and origin of formations in the Schiller-Schickard region of the Moon. Of particular interest are the Schickard light plains, which represent an area of mantled mare basalt, or cryptomare. Here local pre-existing mare basalts were eroded and incorporated into a highlands-rich deposit by eject a from the Orientale Basin. Spectra observations of mature and immature highland and mare surfaces, as well as dark-halo crater materials provide information on the mafic mineralogy of features in the area. Analyses of the '1 micron' absorption band and spectral mixing models indicate that selected spots in the light plains contain on the order of 50 percent mare basalt. CCD image cubes can be used to map the amount of basalt in the light plains and evaluate changes with radial distance from Orientale.

STRONTIUM AND OXYGEN ISOTOPE STUDY OF M-1, M-3 AND M-4 DRILL CORE SAMPLES FROM THE MANSON IMPACT STRUCTURE, IOWA: COMPARISON WITH HAITIAN K-T IMPACT GLASSES Abstract Only **c46**
Joel D. Blum, C. Page Chamberlain, Michael P. Hingston, and Christian

Koeberl (Wien Univ., Austria.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 135-136 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Strontium and oxygen isotope analyses were performed on 8 samples from the M-1, M-3, and M-4 cores recently drilled at the Manson impact structure. The samples were three elastic sedimentary rocks (of probable Cretaceous age) which occurred as clasts within the sedimentary clast breccia, two samples of crystalline rock breccia matrix, and three samples of dolomite and limestone. The Sr-87/Sr-86 (corrected to 65 Ma) ratios were much higher than those in impact glasses from the Haitian Cretaceous-Tertiary (K-T) boundary. Isotope mixing calculations demonstrate that neither the silicate or carbonate rocks analyzed from the Manson crater, or mixtures of these rocks are appropriate source materials for the Haitian impact glasses. However, the Sr-87/Sr-86 (65Ma) ratio and delta O-18 value of the Ca-rich Haitian glasses are well reproduced by mixtures of Si-rich Haitian glass with platform carbonate of K-T age.

Eucrites, howardites, and diogenites have Fe/Mn ratios between 30 and 45, while carbonaceous chondrites have much higher values between 90 and 150. Stolper (1977) first showed that basaltic achondrites could evolve from a precursor chondritic material through simple partial melting. These experiments indicated that chondritic material heated to temperatures near 1180 C with a fugacity of one log unit below the iron-wustite buffer curve, produced a eucritic mineralogy that contained olivine, pigeonite, plagioclase, spinel, glass, and metal. The partial melting experiments of Jurewicz et al. (1992) on an hydrous Murchison and Allende also showed that HED compositions were produceable at temperatures between 1130 C and 1325 C with fugacities below and above the iron-wustite buffer curve. However, the MnO abundances of Jurewicz were too low to produce suitable Fe/Mn ratios for HED's. We present below our results of partial melting experiments on Murchison analogues that involved temperatures between 1180 C and 1580 C and fugacities below the iron-wustite buffer curve. Our experiments resulted in MnO abundances nearly twice that of Jurewicz and indicate that the production of basaltic achondrite-like Fe/Mn ratios from precursor chondritic material are possible. LEW88516 contains excess amounts of radiogenic Ar-40 and Xe-129 that are slightly greater than those observed in ALH77005, but in the same relative proportion as much larger excesses observed in EET79001. Cosmogenic He-3 and Ne-21 abundances in LEW88516 are very similar to those for ALH77005 and are consistent with a common initiation of cosmic ray exposure -2.8 Myr ago for four of the five shergottites. Exposure of these four shergottites could have been under different shielding in a common meteoroid, or in several objects. Author (revised)

Ar-39 - Ar-40 AGES OF ACAPULCOITES AND LODRANITES: EVIDENCE FOR EARLY PARENT BODY HEATING Abstract Only **c46**
D. D. Bogard, D. H. Garrison, T. J. McCoy (Hawaii Univ., Honolulu.), and K. Keil (Hawaii Univ., Honolulu.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 141-142 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

New age dating of acapulcoites (Acapulco, Monument Draw) and lodranites (Gibson) allow us to reconstruct the history of their parent body in a chronological framework. These meteorites originated on a common parent body -4.55 Ga ago. Non-collisional heating caused partial melting, with lodranites having been heated slightly higher than acapulcoites. This parent body cooled to the Ar closure temperature at -4.51 Ga for acapulcoites and -4.48 Ga for lodranites. The difference in ages is consistent with the higher temperature and longer cooling time for lodranites. Cooling probably occurred at a few to tens of deg C/Ma, with slower cooling rates at lower temperatures. Author (revised)

ARROYO EL MIMBRAL, MEXICO, K/T UNIT: ORIGIN AS DEBRIS FLOW/TURBIDITE, NOT A TSUNAMI DEPOSIT Abstract Only **c46**
Bruce F. Bohor and William J. Betterton *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 143-144 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Coarse, spherule-bearing, elastic units have been discovered at 10 marine sites that span the K/T boundary in northeastern Mexico. We examined one of the best exposed sites in Arroyo el Mimbral, northwest of Tampico. The Mimbral outcrop displays a layered elastic unit up to 3 m thick enclosed by marly limestones of the Mendez (Latest Maastrichian) and Velasco (Earliest Danian) Formations. At its thickest point, this channelized elastic unit is comprised of 3 subunits: (1) a basal, poorly-sorted, ungraded calcareous spherule bed 1 m thick containing relict impact glass and shocked mineral grains, (2) a massive set of laminated calcite-cemented sandstones up to 2 m thick with plant debris at its base, (3) capped by a thin (up to 20 cm) set of rippled sandstone layers separated by silty mudstone drapes containing a small (921 pg/g) iridium anomaly. This tripartite elastic unit is conformably overlain by marls of the Velasco Formation. We also visited the La Lajilla site east of Ciudad Victoria; its stratigraphy is similar to Mimbral's, but its elastic beds are thinner and less extensive laterally. The Mimbral elastic unit has been interpreted previously as being deposited by a megawave or tsunami produced by an asteroid impact on nearby Yucatan (Chicxulub crater). However, a presumed 400-m paleodepth of water at the Mimbral site, channeling of the spherule subunit into the underlying Mendez Formation marls, and the overtopping of the basal, spherule-bearing subunit by the laminated sandstone subunit, all suggest a combined debris flow/turbidite origin for this elastic unit similar to that proposed for Upper Pleistocene sand/silt beds occurring elsewhere in the Gulf of Mexico. In this latter model, the sediment source region for the elastic unit is the lower continental shelf and slope escarpment. For the K/T unit at Mimbral, we propose that thick ejecta blanket deposits composed mostly of spherules were rapidly loaded onto the lower shelf and slope from an impact-generated ejecta curtain. K/T SPHERULES FROM HAITI AND WYOMING: ORIGIN, DIAGENESIS, AND SIMILARITY TO SOME MICROTEKTITES Abstract Only **c46**
B. F. Bohor, B. P. Glass (Delaware Univ., Newark.), and W. J. Betterton *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 145-146 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Spherules with relict glass cores in the K/T boundary bed of Haiti allow for a comparison of these bodies with hollow goyazite shells in the K/T boundary claystone of Wyoming and with younger microtektites of the Ivory Coast strewn field. Samples of the Haitian beds from undisturbed sections at Beloc, as determined by Jehanno et al., contain both hollow shells and relict glass cores rimmed by palagonite that has been partially converted to smectite. These palagonite rims developed from hydration zones formed when hot, splash-form droplets of andesitic impact glass were deposited into water. Mutual collisions between these droplets in the ejecta curtain may have formed point-source stresses on their surfaces. Initiation of hydration would be facilitated at these surface stress points and propagated radially into the glass. The inner surface of these merged hemispherical fronts appears mammillary, which is reflected as scalloping in Haitian relict glass cores. Derived from text

THE SOLUBILITY OF GOLD IN SILICATE MELTS: FIRST RESULTS Abstract Only c26
A. Borisov, H. Palme, and B. Spettel *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 147-148 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The effects of oxygen fugacity and temperature on the solubility of Au in silicate melts were determined. Pd-Au alloys were equilibrated with silicate of anorthite-diopside eutectic composition at different T-fO2 conditions. The behavior of Au was found to be similar to that of Pd reported recently. Au solubilities for alloys with 30 to 40 at. percent Au decrease at 1400 C from 12 ppm in air to 160 ppb at a log fO2 = -8.7. The slope of the log(Me-solubility) vs. log(fO2) curve is close to 1/4 for Au and the simultaneously determined Pd suggesting a formal valence of Au and Pd of 1+. Near the IW buffer Pd and Au solubilities become even less dependent on fO2 perhaps reflecting the presence of some metallic Au and Pd. Author (revised)

SI-29 NMR SPECTROSCOPY OF NATURALLY-SHOCKED QUARTZ FROM METEOR CRATER, ARIZONA: CORRELATION TO KIEFFER'S CLASSIFICATION SCHEME Abstract Only c25
M. B. Boslough, R. T. Cygan, and R. J. Kirkpatrick (Illinois Univ., Urbana.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 149-150 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

We have applied solid state Si-29 nuclear magnetic resonance (NMR) spectroscopy to five naturally-shocked Coconino Sandstone samples from Meteor Crater, Arizona, with the goal of examining possible correlations between NMR spectral characteristics and shock level. This work follows our observation of a strong correlation between the width of a Si-29 resonance and peak shock pressure for experimentally shocked quartz powders. The peak width increase is due to the shock-induced formation of amorphous silica, which increases as a function of shock pressure over the range that we studied (7.5 to 22 GPa). The Coconino Sandstone spectra are in excellent agreement with the classification scheme of Kieffer in terms of presence and approximate abundances of quartz, coesite, stishovite, and glass. We also observe a new resonance in two moderately shocked samples that we have tentatively identified with silicon in tetrahedra with one hydroxyl group in a densified form of amorphous silica. MIDPLANE TEMPERATURES IN THE SOLAR NEBULA Abstract Only c92
A. P. Boss *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 151-152 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Cosmochemical analyses of meteorites imply that maximum temperatures in the inner solar nebula were on the order of 1300 K, yet standard viscous accretion disk models predict much lower midplane temperatures (approx. 300 K at 2 AU to 3 AU) in a minimum mass nebula. A second-order accurate radiative hydrodynamics code has been used to construct models of the late-phase solar nebula appropriate for low-mass star formation (M is approximately 10(exp -6) to 10(exp -5) solar-M yr(exp -1). For a minimum mass (0.02 solar-M) nebula and a solar-mass protostar, the new models show that compressional heating due to mass accretion onto the nebula and subsequent vertical contraction of the nebula are sufficient to lead to midplane temperatures T(sub m) greater than 1400 K at 1 AU and T(sub m) greater than 1000 K at 2.5 AU. CHONDRULE FORMATION BY CLUMPY ACCRETION ONTO THE SOLAR NEBULA Abstract Only c92
A. P. Boss and J. A. Graham *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 153-154 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Chondrule textures and compositions appear to require rapid heating of precursor grain aggregates to temperatures in the range 1500 K to 2100 K, cooling times on the order of hours, and episodic and variable intensity events in order to produce chondrule rims and chemically distinct groups. Nebula shock waves have been proposed by Hood and Horanyi as a physical mechanism that may be capable of meeting the meteoritical constraints. Motivated by astronomical observations of the close environments of young stars, we suggest that the source of the nebula shock waves may be clumpy accretion onto the solar nebula - that is, episodic impacts onto the nebula by discrete cloud clumps with masses of at least 10(exp 22) g. If the cloud clumps are massive enough (10(exp 26) g), the resulting shockwave may be able to propagate to the midplane and process precursor aggregates residing in a dust sub-disk. Author (revised)

INITIATING SOLAR SYSTEM FORMATION THROUGH STELLAR SHOCK WAVES c92
A. P. Boss and E. A. Myhill *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 155-156 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Isotopic anomalies in presolar grains and other meteoritical components require nucleosynthesis in stellar interiors, condensation into dust grains in stellar envelopes, transport of the grains through the interstellar medium by stellar outflows, and finally injection of the grains into the presolar nebula. The proximity of the presolar cloud to these energetic stellar events suggests that a shock wave from a stellar outflow might have initiated the collapse of an otherwise stable presolar cloud. We have begun to study the interactions of stellar shock waves with thermally supported, dense molecular cloud cores, using a three spatial dimension (3D) radiative hydrodynamics code. Supernova shock waves have been shown by others to destroy quiescent clouds, so we are trying to determine if the much smaller shock speeds found in, e.g., asymptotic giant branch (AGB) star winds, are strong enough to initiate collapse in an otherwise stable, rotating, solar-mass cloud core, without leading to destruction of the cloud. IMPACT MINERALOGY AND CHEMISTRY OF THE CRETACEOUS-TERTIARY BOUNDARY AT DSDP SITE 576 Abstract Only c46
Jennifer A. Bostwick and Frank T. Kyte *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 157-158 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

We have identified the K/T boundary in pelagic clay sediments from cores at DSDP Site 576 in the western North Pacific. Detailed geochemical and trace mineralogical analyses of this boundary section are in progress and initial results indicate similarities and differences relative to the only other clay core investigated in detail; DSDP Site 596, a locality in the western South Pacific. Peak Ir concentrations of 13 ng/g in DSDP Hole 576B are virtually identical with those observed in the South Pacific, but in the North Pacific this peak is much narrower and the integrated Ir fluence of 85 ng cm(exp -2) is 4 times lower (320 in Hole 596). Of the 34 elements measured, only Ir and Cr were found to have anomalous concentrations in K/T boundary samples. Trace mineral residues were obtained by washing away clays and sequential chemical leaches (including HF) to remove typical hydrogenous and biogenous sediment components (e.g., zeolites and radiolarian opal). We attempted to quantitatively recover the entire trace mineral assemblage for grains greater than 30 micrometers in diameter. Our mineral residues were dominated by two phases: quartz and magnesioferrite spinel. Other non-opaque mineral grains we have positively identified were trace K-feldspar, plagioclase, corundum, and muscovite. Of these only K-feldspar exhibited planar deformation features (PDF). We have not found abundant plagioclase, as in the South Pacific suggesting that this phase was either not preserved in the North Pacific, or that in the south, it has a non-impact (i.e., volcanic) source. PDF in quartz were commonly obscured by secondary overgrowths on the surfaces of quartz grains, presumably from diagenetic reprecipitation of silica dissolved from opaline radiolarian tests that are common in these sediments. However, careful examination revealed that most grains had multiple sets of PDF. Of the 133 quartz grains greater than 30 micrometers analyzed, 62 percent showed evidence of shock. The largest shocked grain recovered to date had a maximum diameter of 160 micrometers, consistent with other sites in the Pacific. Derived from text

COLLISION LIFETIMES AND IMPACT STATISTICS OF NEAR-EARTH ASTEROIDS c90

W. F. Bottke, Jr., M. C. Nolan, and R. Greenberg *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 159-160 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

We have examined the lifetimes of Near-Earth asteroids (NEA's) by directly computing the collision probabilities with other asteroids and with the terrestrial planets. We compare these to the dynamical lifetimes, and to collisional lifetimes assumed by other workers. We discuss the implications of the differences. The lifetimes of NEA's are important because, along with the statistics of craters on the Earth and Moon, they help us to compute the number of NEA's and the rate at which new NEA's are brought to the vicinity of the Earth. Assuming that the NEA population is in steady-state, the lifetimes determine the flux of new bodies needed to replenish the population. Earlier estimates of the lifetimes ignored (or incompletely accounted for) the differences in the velocities of asteroids as they move in their orbits, so our results differ from (for example) Greenberg and Chapman (1983, Icarus 55, 455) and Wetherill (1988, Icarus 76, 1) by factors of 2 to 10. We have computed the collision rates and relative velocities of NEA's with each other, the main-belt asteroids, and the terrestrial planets, using the corrected method described by Bottke et. al. (1992, GRL, in press). We find that NEA's typically have shorter collisional lifetimes than do main-belt asteroids of the same size, due to their high eccentricities, which typically give them aphelia in the main belt. Consequently, they spend a great deal of time in the main belt, and are moving much slower than the bodies around them, making them 'sitting ducks' for impacts with other asteroids. They cross the paths of many objects, and their typical collision velocities are much higher (10-15 km/s) than the collision velocities (5 km/s) among objects within the main belt. These factors combine to give them substantially shorter lifetimes than had been previously estimated. Derived from text

AGE OF POPIGAI IMPACT EVENT USING THE Ar-40 - Ar-39 METHOD Abstract Only c46

R. J. Bottomley and R. A. F. Grieve (Geological Survey of Canada, Ottawa, Ontario.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 161-162 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

The Popigai impact structure of central Siberia is the largest known impact crater in the Commonwealth of Independent States with an original diameter of some 100 km. The age of the crater is constrained by the existing stratigraphy to a period between 5-65 Ma. Attempts to date the impact event using conventional K-Ar on whole rock samples and fission track dating on glasses yield a spread of ages between 30 and 45 Ma. Argon step-heating analyses of several whole-rock samples performed with the Argon Laserprobe at the University of Toronto indicated an age of impact of about 36 Ma. However, a more recently reported Ar-40 - Ar-49 result on glass separated from a suevite sample gave a 65 Ma age and raised the possibility that Popigai was involved with the K/T boundary event. We have pursued further analyses at the University of Toronto on a broader spectrum of Popigai samples. These results confirm an age of about 36 Ma for the formation of this crater, and indicate that Popigai was not associated with the K/T boundary event. Derived from text

MINOR AND TRACE ELEMENT COMPOSITION AND AGE OF YUKON PROBABLE-MICROTEKTITES Abstract Only c90

S. Q. Boundy-Sanders and R. L. Hervig (Arizona State Univ., Tempe.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 163-164 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Major, minor, and trace element composition of the candidate microtektites from Yukon Territory suggest a possible impact site of hydrothermally altered limestone and sand or chert, or possibly a carbonatite. Their REE/chondrite curve is similar in character to, but higher than, shale composites of North America, Australia, and Europe. Relative to these same composites, the Yukon droplets are enriched in Y, F, S, Sr, P, Mn, Mg, and Ca. They are depleted in Rb, Li, Th, Nb, Ti, K, Na, Fe, Si, and Al. Biostratigraphic constraints on the droplets indicate they are Middle to Late Devonian, more likely Middle Devonian, in age. Derived from text

A STRUCTURAL ORIGIN FOR THE CANTALOUPE TERRAIN OF TRITON Abstract Only

Joseph M. Boyce *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 165-166 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Cantaloupe terrain is unique to Triton. It is Triton's oldest terrain and includes about 250,000 km sq. region displaying sparsely cratered, closely spaced, nearly circular dimples about 30-40 km across. This terrain is found on no other planet because, only on Triton the final major global thermal pulse (1) caused completed (or nearly) interior melting resulting in a cooling history where large thermal stresses shattered and contorted a thin, weak lithosphere, and (2) occurred after heavy bombardment so that the surface features were preserved. The cantaloupe terrain is composed of intersecting sets of structures (folds and/or faults) that have developed as a result of global compression generated by volumetric changes associated with cooling of Triton's interior. Further, it is proposed that these structures developed after the period of heavy bombardment, and resulted from the last major global thermal epoch in Triton's unique history (either caused by tidal or radio metric heating). Initially, as the body cooled and the structures formed, their surface topography was most likely modified by thermal relaxation of the warm surface ices. In other bodies like Mercury, thermal stresses generated from global cooling and contraction have resulted in widely spaced thrust faults, whereas on Triton, thermal stresses produced more closely-spaced folds and faults sets. This difference in structural style is probably due to differences in lithospheric properties (thickness, strength, etc.), the magnitude of stress (directly dependent on the thermal history), and when the structures formed, relative to the period of heavy bombardment. TRACE-ELEMENT ABUNDANCES IN SEVERAL NEW UREILITES Abstract Only c25

William V. Boynton and Dolores H. Hill *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 167-168 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Four new ureilites are analyzed for trace-element abundances. Frontier Mountain (FRO) 90054 is an augite-rich ureilite and has high rare earth element (REE) abundances with a pattern expected of augite. FRO 90036 and Acfer 277 have REE patterns similar to the V-shape pattern of other ureilites. Nuevo Mercurio (b) has very high REE abundances, but they look like they are due to terrestrial alteration. The siderophile-element pattern of these ureilites are similar to those of known ureilites. COMPOSITIONAL AND TEXTURAL INFORMATION FROM THE DUAL INVERSION OF VISIBLE, NEAR AND THERMAL INFRARED REMOTELY SENSED DATA Abstract Only c43

Robert A. Brackett and Raymond E. Arvidson *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 169-170 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

A technique is presented that allows extraction of compositional and textural information from visible, near and thermal infrared remotely sensed data. Using a library of both emissivity and reflectance spectra, endmember abundances and endmember thermal inertias are extracted from AVIRIS (Airborne Visible and Infrared Imaging Spectrometer) and TIMS (Thermal Infrared Mapping Spectrometer) data over Lunar Crater Volcanic Field, Nevada, using a dual inversion. The inversion technique is motivated by upcoming Mars Observer data and the need for separation of composition and texture parameters from sub pixel mixtures of bedrock and dust. The model employed offers the opportunity to extract compositional and textural information for a variety of endmembers within a given pixel. Geologic inferences concerning grain size, abundance, and source of endmembers can be made directly from the inverted data. These parameters are of direct relevance to Mars exploration, both for Mars Observer and for follow-on missions. Derived from text

UNEQUILIBRATED, EQUILIBRATED, AND REDUCED AGGREGATES IN ANHYDROUS INTERPLANETARY DUST PARTICLES Abstract Only **c90**
J. P. Bradley *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 171-172 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Track-rich anhydrous IDP's are probably the most primitive IDP's because they have escaped significant post-accretional alteration; they exhibit evidence of (nebular) gas phase reactions; their mineralogy is similar to comet Halley's dust; and some of them exhibit comet-like IR spectral characteristics. However, basic questions about the mineralogy and petrography of anhydrous IDP's remain unanswered, because they contain aggregated components that can be heterogeneous on a scale of nanometers. In some IDP's, aggregates account for greater than 75 percent of the volume of the particle. The aggregates have been systematically examined using an analytical electron microscope (AEM), which provides probe-forming optics and (x-ray and electron) spectrometers necessary to analyze individual nanometer-sized grains. The AEM results reveal at least three mineralogically distinct classes of aggregates in an hydrous IDP's, with mineralogies reflecting significantly different formation/aggregation environments. CARBON ANALYSES OF IDP'S SECTIONED IN SULFUR AND SUPPORTED ON BERYLLIUM FILMS Abstract Only **c25**
J. P. Bradley, L. Keller (National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, TX.), K. L. Thomas (Lockheed Corp., Houston, TX.), T. B. VanderWood, and D. E. Brownlee (Washington Univ., Seattle.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 173-174 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Carbon is the only major element in interplanetary dust whose abundance, distribution and chemical state are not well understood. Information about carbon could clarify the relationship between the various classes of IDP's, conventional meteorites, and sources (e.g., comets vs. asteroids). To date, the most reliable estimates of C abundance in Interplanetary Dust Particles (IDP's) have been obtained by analyzing particles on thick-flat Be substrates using thin-window energy-dispersive spectroscopy in the SEM. These estimates of C abundance are valid only if C is homogeneously distributed, because detected C x-rays originate from the outer 0.1 micrometers of the particle. An alternative and potentially more accurate method of measuring C abundances is to analyze multiple thin sections (each less than 0.1 less than 0.1 micrometers thick) of IDP's. These efforts however, have been stymied because of a lack of a suitable non-carbonaceous embedding medium and the availability of C-free conductive substrates. We have embedded and thin-sectioned IDP's in glassy sulfur, and transferred the thin sections to Be support films approximately 25 nm thick. The sections were then analyzed in a 200 KeV analytical TEM. S sublimes rapidly under vacuum in the TEM, leaving non-embedded sections supported on Be. Apart from quantitative C (and O) analyses, S sectioning dramatically expands the range of analytical measurements that can be performed on a single IDP. Derived from text

MODERN SHELF ICE, EQUATORIAL AEOLIS QUADRANGLE, MARS Abstract Only
G. R. Brakenridge *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 175-176 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

As part of a detailed study of the geological and geomorphological evolution of Aeolis Quadrangle, I have encountered evidence suggesting that near surface ice exists at low latitudes and was formed by partial or complete freezing of an inland sea. The area of interest is centered at approximately -2 deg, 196 deg. As seen in a suite of Viking Orbiter frames obtained at a range of approximately 600 km, the plains surface at this location is very lightly cratered or uncratered, and it is thus of late Amazonian age. Extant topographic data indicate that the Amazonian plains at this location occupy a trough whose surface lies at least 1000 m below the Mars datum. A reasonable hypothesis is that quite recent surface water releases, perhaps associated with final evolution of large 'outflow chasms' to the south, but possibly from other source areas, filled this trough, that ice floes formed almost immediately, and that either grounded ice or an ice-covered sea still persists. A reasonable hypothesis is that quite recent surface water releases, perhaps associated with final evolution of large 'outflow chasms' to the south, but possibly from other source areas, filled this trough, that ice floes formed almost immediately, and that either grounded ice or an ice-covered sea still persists. In either case, the thin (a few meters at most) high albedo, low thermal inertia cover of aeolian materials was instrumental in allowing ice preservation, and at least the lower portions of this dust cover may be cemented by water ice. Detailed mapping using Viking stereopairs and quantitative comparisons to terrestrial shelf ice geometries are underway. Derived from text

MINERALOGY VERSUS BULK COMPOSITION OF THE CARBONACEOUS CHONDRITE CLAST KAIDUN 2 Abstract Only **c90**
F. Brandstaetter, G. Kurat, A. V. Ivanov (Academy of Sciences, USSR, Moscow.), H. Palme (Max-Planck-Inst. fuer Chemie, Mainz, Germany.), and B. Spettel (Max-Planck-Inst. fuer Chemie, Mainz, Germany.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 177-178 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Kaidun is an unusual chondritic meteorite. Its main mass is of CR-type (Kaidun I) and contains CI-like (Kaidun II), EL, and EH clasts. The classification of Kaidun II based on mineralogy and bulk chemical criteria does not allow an unambigious assignment to CI. Here we report on the bulk chemical composition and the mineralogy of the Kaidun II clasts. The results of our investigation show that Kaidun II has some characteristics of both CI and CM chondrites. A possible relationship to the texture and composition of micrometeorites is indicated. The Kaidun II clast shows some conflicting mineralogical and chemical characteristics that do not allow an unambigious assignment to the well established carbonaceous chondrite classes. The overall texture of the matrix-rich clast and morphology of opaques are typical for CI's. Bulk matrix and bulk sample compositions reveal similarities with CM's. In addition, the presence of low-Fe Mn-enriched olivines and the relatively high abundance of enstatite resembles some micrometeorites. Derived from text

A STRUCTURAL AND PETROGRAPHIC INVESTIGATION OF THE PRETORIA SALTPAN IMPACT STRUCTURE Abstract Only **c46**
D. Brandt and W. U. Reimold *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 179-180 Sponsored in part by the Barringer Crater Co. (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The Pretoria Saltpan crater is located in the southern portion of the Bushveld Igneous Complex some 40 km NNW of Pretoria, South Africa, at 25 deg 24 min 30 sec S/28 deg 4 min 59 sec E. The near-circular structure of 1.13 km diameter exhibits a well-preserved, uptilted granite rim. Granitic breccia overlies Karroo sediment in places, indicating a post-Karroo age for the cratering event. The coincidence of the spacial occurrence of the crater with respect to various alkaline and ultramafic intrusives has been the main argument put for yard against an impact origin for the structure. Detailed mapping of the crater rim exposures and the crater environs was carried out and revealed many occurrences of intrusives in the whole region. Structural analysis along the rim revealed the presence of typical impact crater related structures. Comparative petrographic and chemical studies of crater-related and non-related intrusives showed close similarities between these sample suites. Derived from text

GEOPHYSICAL SIGNATURE OF THE PRETORIA SALTPAN IMPACT STRUCTURE AND A POSSIBLE SATELLITE CRATER Abstract Only c46

D. Brandt, R. J. Durrheim, and W. U. Reimold *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 181-182 Sponsored in part by the Barringer Crater Co. (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

The Pretoria Saltpan Crater is located in the southern portion of the Bushveld Igneous Complex, some 40 km NNW of Pretoria, South Africa, at 25 deg 24 min 30 sec S/28 deg 4 min 59 sec E. An origin by impact for this crater structure was recently confirmed. The results of the only gravity reconnaissance carried out over the crater to date failed to support an impact origin. With the aid of recent results obtained from a central drill-core, it was necessary to carry out more geophysical work which would include a gravity profile of higher resolution. A second, smaller, circular depression (about 400 m in diameter) to the SW of the crater is suggestive of a twin crater. This site had never been investigated, and thus various geophysical surveys were conducted. Derived from text

CARBONACEOUS CHONDRITE CLASTS IN THE KAPOETA HOWARDITE Abstract Only c46

Adrian J. Brearley and J. J. Papike *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 183-184 (For primary document see N94-12015 01-91)

(Grant NAG9-497)

Avail: CASI HC A01/MF A06

A petrographic and mineralogical study of a number of carbonaceous chondrite clasts in the Kapoeta howardite has been carried out. Most of the clasts have mineralogical and chemical properties which link them to the CM carbonaceous chondrites. Some clasts contain chondrules which often have well-developed fine-grained rims, but many have been extensively brecciated. PCP-rich objects are common and pentlandite and pyrrhotite also occur. Calcite has also been found. The remainder of the clasts are extremely fine-grained and appear to be closely related to CI carbonaceous chondrites. In these clasts magnetite framboids are common and finegrained sulfides and magnetite occur disseminated throughout the matrix. Derived from text

CHONDRITE THERMAL HISTORIES FROM LOW-CA PYROXENE MICROSTRUCTURES: AUTOMETAMORPHISM VERSUS PROGRADE METAMORPHISM REVISITED Abstract Only c90

Adrian J. Brearley, Rhian H. Jones, and J. J. Papike *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 185-186 (For primary document see N94-12015 01-91)

(Grant NAG9-497)

Avail: CASI HC A01/MF A06

In order to constrain the thermal histories of chondritic meteorites, a detailed study of the microstructures of low-Ca pyroxenes produced experimentally and in types 4 and 5 ordinary chondrites was carried out. Cooling experiments on synthetic MgSiO3 at cooling rates between 2 and 10000 C/hr from the protopyroxene stability field into that of orthopyroxene (OPX) were performed and the products of these experiments were annealed for a variety of annealing times. There are clear microstructural differences between samples which were cooled and those which were subsequently annealed. A comparison of the microstructures observed in the experimental samples with those in H4-5 ordinary chondrites shows that they cannot have experienced a single stage cooling history, as proposed for the autometamorphism model. SXRF DETERMINATION OF TRACE ELEMENTS IN CHONDRULE RIMS IN THE UNEQUILIBRATED CO3 CHONDRITE, ALH A77307 Abstract Only c90

Adrian J. Brearley, Sasa Bajt (Brookhaven National Lab., Upton, NY.), Steve R. Sutton (Brookhaven National Lab., Upton, NY.), and J. J. Papike *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 187-188 (For primary document see N94-12015 01-91)

(Grants NAG9-437; NAG9-106)

Avail: CASI HC A01/MF A06

The concentrations of Ni, Cu, Zn, Ga, Ge, and Se in five chondrule rims in the CO3 chondrite ALH A77307 (3.0) using the synchrotron x-ray fluorescence (SXRF) microprobe at Brookhaven National Laboratory were determined. The data show that the trace element chemistry of rims on different chondrules is remarkably similar, consistent with data obtained for the major elements by electron microprobe. These results support the idea that rims are not genetically related to individual chondrules, but all sampled the same reservoir of homogeneously mixed dust. Of the trace elements analyzed Zn and Ga show depletions relative to CI chondrite values, but in comparison with bulk CO chondrites all the elements are enriched by approximately 1.5 to 3.5 x CO. The high concentrations of the highly volatile elements Se and Ga and moderately volatile Zn (1.5 to 2 x CO) in rims show that matrix is the major reservoir of volatile elements in ALH A77307. MARTIAN PARTICLE SIZE BASED ON THERMAL INERTIA CORRECTED FOR ELEVATION-DEPENDENT ATMOSPHERIC PROPERTIES Abstract Only c90

N. T. Bridges *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 189-190 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Thermal inertia is commonly used to derive physical properties of the Martian surface. If the surface is composed of loosely consolidated grains, then the thermal conductivity derived from the inertia can theoretically be used to compute the particle size. However, one persistent difficulty associated with the interpretation of thermal inertia and the derivation of particle size from it has been the degree to which atmospheric properties affect both the radiation balance at the surface and the gas conductivity. These factors vary with atmospheric pressure so that derived thermal inertias and particle sizes are a function of elevation. By utilizing currently available thermal models and laboratory information, a fine component thermal inertia map was convolved with digital topography to produce particle size maps of the Martian surface corrected for these elevation-dependent effects. Such an approach is especially applicable for the highest elevations on Mars, where atmospheric back radiation and gas conductivity are low. Author (revised)

MULTIPLE NITROGEN COMPONENTS IN LUNAR SOIL SAMPLE 12023 Abstract Only

D. R. Brilliant, I. A. Franchi, and C. T. Pillinger *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 191-192 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Nitrogen is one of the enigmatic elements in lunar soils and breccias. The large range in (delta)N-15 values found within lunar soils was initially attributed to a secular increase in the N-15/N-14 ratio of 50 percent within the solar corona, and hence in the implanted nitrogen within the lunar regolith. However, more recent explanations have proposed a two (or many) component mixing model of solar wind nitrogen with some hypothetical non-solar components. Such components could include indigenous lunar nitrogen, nitrogen contained in interstellar grains in primitive meteorites, and magnetospheric nitrogen from the terrestrial atmosphere. To understand the makeup of multi-component mixtures it is advantageous to have carbon and noble gas data measured simultaneously, particularly in the case of lunar soils, where the solar wind is a likely fundamental contributor of nitrogen. To this end, a new nitrogen instrument was adapted to give some of the desired data in parallel. Conjoint measurements of N abundance and (delta)N-15 together with N/Ar-36 and Ar-36/Ar-38 ratios obtained during a stepped combustion of lunar soil 12023. The results are preliminary to a much more comprehensive investigation of well characterized fractions of the sample which we still have available from a previous study. Stepped combustion of a sample of 12023,7 yielded 94 ppm nitrogen with a (delta)N-15 = +22.2 percent, as well as the characteristic heavy-light-heavy pattern observed for lunar samples. The low temperature maximum was +75.1 percent at 550 C, the minimum at 800 C with (delta)N-15 = -16.7 percent and the high temperature (delta)N-15 peak is +90.6 percent at 1250 C. The major releases of nitrogen occurred between 650 C - 800 C in the form of a double peak; a third, substantial release occurred at 1150 C yielding 14.2 ppm of nitrogen coinciding with a small but recognizable drop in (delta)N-15 against a regularly increasing trend. A REEXAMINATION OF AMINO ACIDS IN LUNAR SOIL Abstract Only
K. L. F. Brinton, J. L. Bada, and J. R. Arnold (California Univ., San Diego, La Jolla.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 193-194 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Amino acids in lunar soils provide an important indicator of the level of prebiotic organic compounds on the moon. The results provide insight into the chemistry of amino acid precursors, and furthermore, given the flux of carbonaceous material to the moon, we can evaluate the survival of organics upon impact. The amino acid contents of both hydrolyzed and unhydrolyzed hot-water extracts of Apollo 17 lunar soil were determined using ophthaldialdehyde/N-acetyl cysteine (OPA/NAC) derivatization followed by HPLC analysis. Previous studies of lunar amino acids were inconclusive, as the technique used (derivatization with ninhydrin followed by HPLC analysis) was unable to discriminate between cosmogenic amino acids and terrestrial contaminants. Cosmogenic amino acids are racemic, and many of the amino acids found in carbonaceous meteorites such as Murchison, i.e., alpha-amino-i-butyric acid (aib), are extremely rare on Earth. The ninhydrin method does not distinguish amino acid enantiomers, nor does it detect alpha-alkyl amino acids such as aib, whereas the OPA/NAC technique does both. Author (revised)

THE SPECTRAL EFFECTS OF SUBSOLIDUS REDUCTION OF OLIVINE AND PYROXENE Abstract Only **c25**
D. T. Britt *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 195-196 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The surfaces of atmosphereless bodies are subjected to a variety of chemical, thermal, accretionary, and shock processes related to their regolith environment. These processes are responsible for a number of alterations that occur in regoliths. Alterations include particle size commutation, implantation of solar wind gases, formation of agglutinates, spectral darkening, and, in the lunar case, the development of the very strong red continuum slope in the visible and near infrared spectra. A great deal of work has pointed to the role of agglutinates as the principal agent for darkening and reddening the lunar soil. The measures of regolith maturity are strongly linked to the accumulation of agglutinates. Recent work has suggested that the finest fractions of agglutinitic glass are major source of the spectral red slope. In particular, the red slope is most strongly associated with the agglutinitic glasses that are rich in blebs of sub-micron sized metal particles. It is thought that these metal particles, because of their size and scattering efficiently relative to the wavelength of light, are responsible for the red continuum slope. This fine fraction of metal particles is produced primarily by reduction of Fe(+2) from silicates. One mechanism for the reduction process is the reaction of solar implanted wind protons with the regolith soil during impact events. In this case the presence of hydrogen creates a reducing environment and the thermal pulse from the impact greatly speeds the reaction kinetics. To explore other reducing and thermal environments a series of experiments were done using samples in evacuated capsules buffered by Tantalum and heated to subsolidus temperatures. Author (revised)

THE 1.2 TO 3.5 MICRONS OBSERVATIONS OF ASTEROID 4179 TOUTATIS Abstract Only **c90**
D. T. Britt, E. S. Howell, J. F. Bell (Hawaii Univ., Honolulu.), and L. A. Lebofsky *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 197 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The close Earth approach of the Apollo asteroid 4179 Toutatis during the winter of 1992-1993 provided a unique opportunity for detailed ground-based observations of a near earth asteroid (NEA). Because of their relatively small size NEA's are usually far too faint to be observable by most ground-based instruments. This opposition by Toutatis was, however, exceptionally favorable. Toutatis approached within 0.03 AU of Earth and was as bright as 11th visual magnitude. This made the object observable in a wide variety of wavelengths including radar, thermal IR, near IR, and visual. Author (revised)

FLEXURE AND THE ROLE OF INPLANE FORCE AROUND CORONAE ON VENUS Abstract Only
C. David Brown and Robert E. Grimm *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 199-200 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Large coronae on Venus, such as Artemis and Latona, are rimmed by conspicuous trenches and associated outer rises. Sandwell and Schubert have observed that these systems resemble terrestrial subduction zones in planform and have succeeded in fitting an elastic plate bending equation to the inferred flexural topography. However, the first zero crossing bending moments required are -2.5 x 10(exp 17) N for Artemis and -5.0 x 10(exp 16) N for Latona. Since these moments are similar in magnitude to those of subducting slabs on Earth, a rollback subduction mechanism was proposed to explain the flexure around the largest coronae, although a differential thermal subsidence model is sufficient to account for the topography around some coronae. The purpose is to investigate the effect of inplane force as a possible alternative to large applied moments in producing flexure at Artemis and Latona. The close correlation of gravity to topography on Venus implies the absence of a low viscosity zone and the strong coupling of the lithosphere to mantle convection. If coronae are the surface manifestations of mantle plumes, they may be the sites of active convective stress coupling. As the upwelling reaches the lithosphere, it spreads radially outward, inducing shear tractions on the base of the plate. In addition, the hot, expanding corona may load the surrounding plate horizonally. Both the basal shear stresses and radial loading can be treated as an equivalent compressive inplane force in the mechanical lithosphere, which contributes to the bending of the outlying plate. Using a model that relates inplane force to the measured gravity anomalies, a rough value of the inplane force at Artemis was calculated. Recent Pioneer Venus spherical harmonic gravity models indicate a geoid anomaly of about 75 m over Artemis, which corresponds to an estimated inplane force on the order of -1x10(exp 13) N/m. The gravity model is unable to resolve Latona, but an inplane force of similar dimensions is assumed. The maximum possible inplane force based on the expected rheology can be constrained by using the approximate 5 K/km thermal gradient inferred from the best fit 30 km elastic plate at Artemis and Latona. For a dry olivine flow law in the upper mantle, the compressional load limit of the 60 km thick mechanical lithosphere is -4 x 10(exp 13) N/m. This value is equivalent to a load of -8 x 10(exp 13) N/m on a 30 km thick elastic plate. Author (revised)

VISCOUS RELAXATION OF THE MOHO UNDER LARGE LUNAR BASINS Abstract Only
C. David Brown and Robert E. Grimm *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 201-202 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Viscously relaxed topography on the Moon is evidence of a period in lunar history of higher internal temperatures and greater surface activity. Previous work has demonstrated the viscous relaxation of the Tranquilitatis basin surface. Profiles of the lunar Moho under nine basins were constructed from an inversion of lunar gravity data. These profiles show a pattern of increasingly subdued relief with age, for which two explanations have been proposed. First, ancient basins may have initially had extreme Moho relief like that of younger basins like Orientale, but, due to higher internal temperatures in early lunar history, this relief viscously relaxed to that observed today. Second, ductile flow in the crust immediately after basin formation resulted in an initially shallow basin and subdued mantle uplift. The intent is to test the first hypothesis. Author (revised)

DETERMINING THE RELATIVE EXTENT OF ALTERATION IN CM CHONDRITES Abstract Only c90
Lauren B. Browning, Harry Y. McSween, Jr., and Michael Zolensky (National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, TX.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 203-204 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The aqueous alteration of CM chondrites provides a record of the processes attending the earliest stages of parent body evolution. However, resolving the alteration pathways of chondritic evolution requires a means for distinguishing the relative extent of alteration that individual samples have experienced. Three new indices for gauging the relative degree of alteration in CM chondrites based on modal and compositional analyses of 7 CM falls were proposed. The proposed alteration parameters are consistent with the basic tenets of several previous models and correlate with additional indices to produce an integrated method for determining the relative extent of alteration. The model predicts the following order of progressive alteration: Murchison (MC) is less than or equal to Bells (BL) is less than Murray (MY) is less than Cochabamba (CC) is less than Mighei (MI) is less than Nogoya (NG) is less than or equal to Cold Bokkeveld (CB). The broad range of CM phyllosilicate compositions observed within individual meteorites is fundamental to the characterization of the aqueous alteration process. Chemical analyses of CM phyllosilicates suggest that these phases became systematically enriched in Mg and depleted in Fe with increasing alteration. Author (revised)

IDENTIFICATION OF COMETARY AND ASTEROIDAL PARTICLES IN STRATOSPHERIC IDP COLLECTIONS Abstract Only c90
D. E. Brownlee, D. J. Joswiak, S. G. Love, A. O. Nier (Minnesota Univ., Minneapolis.), D. J. Schlutter (Minnesota Univ., Minneapolis.), and J. P. Bradley (MVA, Inc., Norcross, GA.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 205-206 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

He release temperature curves were determined for a specially processed set of 5 microns to 15 microns stratospheric IDP's whose masses, densities, and compositions were accurately measured. The He release temperature in combination with atmospheric entry calculations yields a most probable entry velocity for each particle and association with either an asteroidal (low velocity) or cometary (high velocity) origin. It was found that over half of the 5-15 microns IDP's have entry velocities consistent with asteroidal origin and that at least 20 percent have cometary origins. A few of the asteroidal particles are porous aggregates and it appears that there may be close material similarities among some primitive asteroids and comets. In the processing of individual 5 microns IDP's and determination of entry velocities, a few dozen microtome slices that can be used for a variety of detailed TEM, IR, and ion probe studies were preserved. These procedures provide laboratory samples that can be generically associated with asteroids and comets and are in a sense a limited sample return mission from these primitive bodies. QUANTIFYING THE EFFECT OF RHEOLOGY ON PLAN-VIEW SHAPES OF LAVA FLOWS Abstract Only c46
B. C. Bruno, G. J. Taylor, and R. M. C. Lopes-Gautier (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 207-208 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

This study aims at quantifying the effect of rheology on the plan-view shapes of lava flows. Plan-view shapes of lava flows are important because they reflect the processes governing flow emplacement and may provide insight into lava flow rheology and dynamics. In our earlier investigation, it was reported that plan-view shapes of tholeite basalts are fractal, having a characteristic shape regardless of scale. It was also found one could use the fractal dimension (a parameter which quantifies flow margin convolution) to distinguish between the two major types of basalts: a'a and pahoehoe. Encouraged by these earlier results, a similar method for use on silicic flows are being developed and our preliminary work is presented. Author (revised)

THE EET87513 CLAST N: A CM2 FRAGMENT IN AN HED POLYMICT BRECCIA Abstract Only
P. C. Buchanan, M. E. Zolensky (National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, TX.), A. M. Reid, and R. A. Barrett (Lockheed Engineering and Sciences Co., Houston, TX.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 209-210 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Xenoliths of material resembling carbonaceous chondrites have been found in several HED polymict breccias. Most workers concluded that these clasts are related to CM2 meteorites on the basis of texture, bulk composition, and mineralogy. Data on clast N, a carbonaceous chondrite fragment from the howardite EET87513 large enough (approximately 4x5mm on the surface of the slab from which it was separated) to extract bulk samples for INAA and oxygen isotope analysis and to provide a thin section for electron microprobe, SEM, and TEM analysis is reported. Preliminary data for this clast were previously reported. INAA was performed at Oregon State University and bulk oxygen isotopic composition was determined at the University of Chicago. These data confirm that EET87513 clast N is a fragment of CM2 material. Author (revised)

CAN WEAK CRUST EXPLAIN THE CORRELATION OF GEOID AND TOPOGRAPHY ON VENUS? Abstract Only
W. Roger Buck (Iceland Univ., Reykjavik.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 211-212 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The effect on geoid and topography of low viscosity crust overlying a steady-state convecting mantle is estimated under the assumption that the shear between crust and mantle does not alter the mantle flow. The weak crustal layer can change the sign of the geoid to topography ratio (admittance). The positive long wavelength admittance for Venus is consistent with a weak crust overlying a mantle with a viscosity that increases strongly with depth. The accepted interpretation of the strong positive correlation of geoid and topography on Venus, is that the convecting mantle of Venus has a constant viscosity with depth. Topography results from vertical normal stresses caused by mantle convection and highlands occur where mantle upwells. For topography to be supported by normal stress, the time scale for crustal flow must be long compared to the time scale for changes in the pattern of mantle flow. Because the high surface temperature of Venus may cause the crust to have a low viscosity, this assumption may be false. Topography should then be dominated by shear coupling between the crust and mantle. In the absence of a crustal layer, convection in a constant viscosity layer gives rise to a geoid anomaly that correlates positively with surface topography. When the viscosity in the layer increases with depth by several orders of magnitude, the surface topography and geoid anomaly become anti-correlated. Author (revised)

VENUS RESURFACING RATES: CONSTRAINTS PROVIDED BY 3-D MONTE CARLO SIMULATIONS Abstract Only
M. A. Bullock, D. H. Grinspoon, and J. W. Head (Brown Univ., Providence, RI.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 213-214 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

A 3-D Monte Carlo model that simulates the evolving surface of Venus under the influence of a flux of impacting objects and a variety of styles of volcanic resurfacing was implemented. For given rates of impact events and resurfacing, the model predicts the size-frequency and areal distributions of surviving impact craters as a function of time. The number of craters partially modified by volcanic events is also calculated as the surface evolves. It was found that a constant, global resurfacing rate of approximately 0.4 km(sup 3)/yr is required to explain the observed distributions of both the entire crater population, and the population of craters partially modified by volcanic processes. SCALLOPED MARGIN DOMES: WHAT ARE THE PROCESSES RESPONSIBLE AND HOW DO THEY OPERATE?
M. H. Bulmer, J. E. Guest, G. Michaels (Jet Propulsion Lab., California Inst. of Tech., Pasadena.), and S. Saunders (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 215-216 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Studies of scalloped margin domes (SMD) indicate the scallops are the result of slope failure. SMD's have similar but smaller average diameters (26.5 km) to unmodified domes (29.8 km), and the majority plot at altitudes ranging from 0.5-4.7 km, relative to the mean planetary diameter. A range of morphological types exist from those least modified to those that show heavy modification. Of the 200 SMD's examined, 33 have clearly discernible debris aprons. Examination and comparison of debris aprons with mass movement features on the Moon, Mars, and in sub-aerial and submarine environments on Earth using H/L against area (km(sup 2)), suggests there are three main types of failure; debris avalanche, slumps, and debris flow. The five examples representing the morphological range within the SMD's, show the different modified forms and the different types of slope failures that have occurred. Author (revised)

YANA RING STRUCTURE, NORTH-EASTERN SIBERIA: A POSSIBLE COUNTERPART OF CORONAE ON VENUS Abstert Only **c46**
G. A. Burba *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 217-218 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

An arch of Verkhoyansky Range in NE Siberia, Russia is considered as W and S parts of the rim of the large ring structure, referred hereafter as Yana Ring Structure (YRS). It has general appearance similar to coronae on Venus and could be considered as the terrestrial counter part of coronae. The structure is located between 63 and 70 deg N, 125 and 140 deg E. The outer diameter of YRS (between the rim feet) is 680-700 km. The rim crest diameter is 500-520 km. The inner diameters (between the inner feet of the rim) is 320-350 km. The rim of YRS consist of the following topographic features: W segment is Orulgan Range (N part of Verkhoyansky Range), SW and S segments consist of S part of Verkhoyansky Range, SE segment is Elginskoye Ploskogorye (Tableland), E segment is Chersky Range (its part W of Indigirka River), NE segment is Selennyakhsky Range, and NW segment is Kular Range. Inside this ring of mountains Yanskoye Ploskogorye (Tableland) is located. The circular outlines of YRS are marked with the large river valleys located outside: Lena River (lower of Aldan River mouth) is located W from YRS, Aldan River (lower of Amga River mouth) is from S, Indigirka River (between 64 and 67 deg N lat) is from E, and Selennyakh River (the part running N to S) is from NE. The ring patterns inside the mountaineous rim of YRS are marked with the tributaries of Yana River. The largest ring here, 300 km in diameter, consists of Bytangay (with Bellyakh) River at W, Nelgese and Derbeke Rivers at S/SE, and Tuostakh River at E. The typical altitudes of YRS mountain rim are 1000-2000 m. The maximal ones are: 2400 m in W part of the rim, 2300 m in S, 1600 m in SE, 2200-2500 m in E, and 1300-1500 m in N. The central part of YRS have typical altitudes of 400-600 m. There are lowlands with altitudes 50-200 m to the S, W, N, and NW outside YRS Oymyakonskoye Nagorye (Highland) is located SE of YRS at 500-1500 m altitudes. It should be recognized from this description YRS have a general appearance of circular highland with its central plateau located 1000-2000 m lower than surrounding mountain rim, but 300-400 m higher than plains of lowlands located outside the rim. Such topographic patterns are typical for coronae on Venus. The diameter of YRS is equal to the largest coronae on Venus. There are only 3 or 4 structures of such or larger size on the whole Venus. This calls to compare morphology and geologic evolution of YRS with morphology and models of coronae evolutions especially the largest ones, to search the similarities and/or differences in geologic histories of the structures on the Earth and Venus. RUSSIA'S CONTRIBUTION TO REGIONAL GEOLOGIC MAPPING OF VENUS Progress Report, 1992 Abstract Only
G. A. Burba, N. N. Bobina, and V. P. Shashkina *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 219-220 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Geologic maps in Magellan C1-format were produced by six geologists and three cartographer in Russia during 1992. More sheets are in progress. The work is coordinated by Vernadsky Institute. The Magellan SRR images in form of C1-format photomaps were used as a base for geologic-geomorphic regional mapping of Venus at approximately 1:8,000,000 scale. This work took place in Russia at Vernadsky Institute and at the Department of Geology, Lomonosov Moscow University. The aim is to produce a preliminary geologic survey of Venus with the new high resolution images obtained by Magellan. It took place at the cartographic division, Laboratory of Comparative Planetology and Meteoritics, Vernadsky Institute, Russsia's Academy of Sciences. Author (revised)

HOW DIVERSE IS THE ASTEROID BELT? Abstract Only **c90**
Thomas H. Burbine and Jeffrey F. Bell (Hawaii Univ., Honolulu.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 223-224 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

For approximately twenty years, many different asteroid taxonomies, which used many different observational data sets, have been developed to try to group asteroids into classes that contain members with similar spectral characteristics. However, to understand the structure of the asteroid belt, the resulting classes are only useful if they are grouping together asteroids with somewhat similar mineralogies and thermal histories. Until recently, these taxonomies have focused on spectral reflectance data from 0.3 to 1.1 microns and visual albedo. But in the last five years, observational data sets (e.g., 0.8 to 2.5 microns spectra, CCD spectra, 3 microns spectra, and radar albedos) for a small number of asteroids were compiled that can give a better mineralogical interpretation, but whose use in asteroid taxonomy was relatively limited. Analyses of these 'supplementary' data sets show that most asteroid classes contain members with different compositions and/or thermal histories. To understand the diversity of the asteroid belt, the number of objects with these observations must be expanded and used in the next generation of taxonomies. Author (revised)

STUDIES OF THE RELEASE OF RADIOGENIC Xe-129 FROM BJURBOELE: EVIDENCE AGAINST SIMPLE DIFFUSION MODELS Abstract Only **c90**
M. K. Burkland, T. D. Swindle, and S. L. Baldwin *In* Lunar and Planetary

Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 225-226 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The I-Xe system, based on the decay of 15.7 Ma I-129, is a potentially precise chronometer of early solar system events. However, it is not known how the system responded to thermal events during the post-formation histories of ordinary chondrites, severely limiting the usefulness of this system. Isothermal experiments on Bjurbole for different heating durations suggest that at least three domains are responsible for the thermal release of radiogenic Xe-129 (Xe*-129) and that the system may be less susceptible to thermal resetting than some calculations indicated. Two scenarios for the release of Xe*-129 were proposed. In one, the mobility of Xe*-129 is governed by diffusion in mineral grains. This leads to predicted closure temperatures comparable to, or less than, metamorphic temperatures. In the second, mineral grains that solidified at specific temperatures trapped I-129 within them, and the resulting Xe*-129 is only released when those minerals melt, such that isotopic closure occurs at the temperature of solidification. A PATTERN RECOGNITION SYSTEM FOR LOCATING SMALL VOLVANOES IN MAGELLAN SAR IMAGES OF VENUS Abstract Only
M. C. Burl, U. M. Fayyad, P. Smyth, J. C. Aubele (Brown Univ., Providence, RI.), and L. S. Crumpler (Brown Univ., Providence, RI.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 227-228 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The Magellan data set constitutes an example of the large volumes of data that today's instruments can collect, providing more detail of Venus than was previously available from Pioneer Venus, Venera 15/16, or ground-based radar observations put together. However, data analysis technology has not kept pace with data collection and storage technology. Due to the sheer size of the data, complete and comprehensive scientific analysis of such large volumes of image data is no longer feasible without the use of computational aids. Our progress towards developing a pattern recognition system for aiding in the detection and cataloging of small-scale natural features in large collections of images is reported. Combining classical image processing, machine learning, and a graphical user interface, the detection of the 'small-shield' volcanoes (less than 15km in diameter) that constitute the most abundant visible geologic feature in the more that 30,000 synthetic aperture radar (SAR) images of the surface of Venus are initially targeted. Our eventual goal is to provide a general, trainable tool for locating small-scale features where scientists specify what to look for simply by providing examples and attributes of interest to measure. This contrasts with the traditional approach of developing problem specific programs for detecting Specific patterns. The approach and initial results in the specific context of locating small volcanoes is reported. It is estimated, based on extrapolating from previous studies and knowledge of the underlying geologic processes, that there should be on the order of 10(exp 5) to 10(exp 6) of these volcanoes visible in the Magellan data. Identifying and studying these volcanoes is fundamental to a proper understanding of the geologic evolution of Venus. However, locating and parameterizing them in a manual manner is forbiddingly time-consuming. Hence, the development of techniques to partially automate this task were undertaken. The primary constraints for this particular problem are that the method must be reasonably robust and fast. Unlike most geological features, the small volcanoes of Venus can be ascribed to a basic process that produces features with a short list of readily defined characteristics differing significantly from other surface features on Venus. For pattern recognition purposes the relevant criteria include (1) a circular planimetric outline, (2) known diameter frequency distribution from preliminary studies, (3) a limited number of basic morphological shapes, and (4) the common occurrence of a single, circular summit pit at the center of the edifice. SOURCES OF Na FOR THE Io ATMOSPHERE Abstract Only
D. S. Burnett, Susan B. Ellis, A. Rice, and S. Epstein *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 229-230 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The physics and geology of Io have been extensively studied, but there has been little discussion of the chemistry. Relatively little is known about Io chemistry, but there are constraints. Further, it will be a long time before improvements will result from direct observation, given the severe difficulties with the Galileo mission. Via laboratory simulation experiments, plausible thermochemical and photochemical processes which determine the nature and amounts of surface constituents of Io are explored. The well-known density of Io shows that the planet overall is rocky. Because the orbit of Io is well within the magnetosphere of Jupiter and because Io only has a thin, transient SO2 atmosphere, the surface is continually sputtered with magnetospheric ions. Complex processes ionize and accelerate the Io surface atoms to keV and MeV energies. Remarkably, only S, O, and Na ions were found by Voyager. Sputtering also produces an atomic cloud of Na and S (O not observable) with a trace of K. Both gaseous and solid SO2 are known from spectroscopic studies. A trace of H2S and possibly CO2 are present. Geologic features are interpreted in terms of elemental S, but there is no direct evidence for this constituent. We thus have a rocky planet which does not have rocks on the surface. Our general goal is to understand the cycling of Na, S, and O through the crust and atmosphere on present-day Io and to understand how Io evolved to this state. A specific objective was to determine the phases on the surface which are the source of the Na in the atmosphere of Io.

CHEMICAL WEATHERING ON MARS: RATE OF OXIDATION OF IRON DISSOLVED IN BRINES Abstract Only
Roger G. Burns *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 231-232 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Salts believed to occur in Martian regolith imply that brines occur on Mars, which may have facilitated the oxidation of dissolved Fe(2+) ions after they were released during chemical weathering of basaltic ferromagnesian silicate and iron sulfide minerals. Calculations show that the rate of oxidation of Fe(2+) ions at -35 C in a 6M chloride-sulfate brine that might exist on Mars is about 10(exp 6) times slower that the oxidation rate of iron in ice-cold terrestrial seawater. VENUS MOUNTAIN-TOP MINERALOGY: MISCONCEPTIONS ABOUT PYRITE AS THE HIGH RADAR-REFLECTING PHASE Abstract Only
Roger G. Burns and DArcy W. Straub *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 233-234 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Altitude-dependent, high radar-reflectivity surfaces on Venus are observed on most mountainous volcanic terranes above a planetary radius of about 6054 km. However, high radar-reflectivity areas also occur at lower altitudes in some impact craters and plain terranes. Pyrite (FeS2) is commonly believed to be responsible for the high radar reflectivities at high elevations on Venus, on account of large dielectric constants measured for sulfide-bearing rocks that were erroneously attributed to pyrite instead of pyrrhotite. Pentlandite-pyrrhotite assemblages may be responsible for high reflectivities associated with impact craters on the Venusian surface, by analogy with Fe-Ni sulfide deposits occurring in terrestrial astroblemes. Mixed-valence Fe(2+)-Fe(3+) silicates, including oxyhornblende, oxybiotite, and ilvaite, may contribute to high radar reflecting surfaces on mountain-tops of Venus. Author (revised)

BUOYANT SUBDUCTION ON VENUS: IMPLICATIONS FOR SUBDUCTION AROUND CORONAE Abstract Only
J. D. Burt and J. W. Head *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 235-236 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Potentially low lithospheric densities, caused by high Venus surface and perhaps mantle temperatures, could inhibit the development of negative buoyancy-driven subduction and a global system of plate tectonics/crustal recycling on that planet. No evidence for a global plate tectonic system was found so far, however, specific features strongly resembling terrestrial subduction zones in planform and topographic cross-section were described, including trenches around large coronae and chasmata in eastern Aphrodite Terra. The cause for the absence, or an altered expression, of plate tectonics on Venus remains to be found. Slab buoyancy may play a role in this difference, with higher lithospheric temperatures and a tendency toward positive buoyancy acting to oppose the descent of slabs and favoring under thrusting instead. The effect of slab buoyancy on subduction was explored and the conditions which would lead to under thrusting versus those allowing the formation of trenches and self-perpetuating subduction were defined. Applying a finite element code to assess the effects of buoyant forces on slabs subducting into a viscous mantle, it was found that mantle flow induced by horizontal motion of the convergent lithosphere greatly influences subduction angle, while buoyancy forces produce a lesser effect. Induced mantle flow tends to decrease subduction angle to near an under thrusting position when the subducting lithosphere converges on a stationary overriding lithosphere. When the overriding lithosphere is in motion, as in the case of an expanding corona, subduction angles are expected to increase. An initial stage involved estimating the changes in slab buoyancy due to slab healing and pressurization over the course of subduction. Modeling a slab, descending at a fixed angle and heated by conduction, radioactivity, and the heat released in phase changes, slab material density changes due to changing temperature, phase, and pressure were derived.

THE ORIGIN OF VENUSIAN CHANNELS: MODELLING OF THERMAL EROSION BY LAVA Abstract Only
D. B. J. Bussey, S-A. Sorensen, and J. E. Guest *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 237-238 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Magellan imagery has revealed that channels, apparently volcanic in origin, are abundant on the surface of Venus. There has been much debate about the origin of these channels. Are they the result of erosional (either thermal or mechanical) or constructional processes? A common characteristic of the simple sinuous channels is that they show evidence of erosion near their source and then become purely constructional, forming levees and in some cases roofing over completely. One method of showing that thermal erosion is capable of producing the type of channels seen is to use computer modeling incorporating the physical conditions on Venus and the physical characteristics of the different types of lava that may have been erupted. It is possible to calculate, relatively easily, two channel parameters. The first is the erosion rate, which combined with eruption duration, gives depth. The second is for how long after leaving the source the erupted lava will continue to be capable of thermal erosion before constructional processes dominate. Making assumptions about the rheology of the lava (e.g., assume it behaves as a Bingham plastic) along with the slope angle yields a flow velocity and therefore a distance over which thermal erosion will take place. Due to the resolution (both vertical and horizontal) of the Magellan altimetric data, the distance from the source that the channel is erosional can be much more accurately measured than the depth of the channel. This will remain the case until stereo imagery becomes available for large areas of the planet. Author (revised)

Avail: CASI HC A01/MF A06

In an attempt to classify the nature of volatiles within interplanetary dust particles (IDP's), 14 IDP's using a laser microprobe/mass spectrometer (LM/MS) technique were studied. Volatile abundances and distributions found for the IDP's are compared with those measured for carbonaceous chondrites in order to determine if the IDP's are related to the parent bodies of these primitive meteorites. AN ANCIENT INNER LAKE IN MAADIM VALLIS Abstract Only
N. A. Cabrol, E. A. Grin, A. Dollfus, and G. Dawidowicz (Paris Univ., France.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 241-242 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The survey of Ma'adim Vallis and crater Gusev area by the new topographic Aeolis southeast map allows to document the hydrodynamics processes which occurred in the valley. The inner Ma'adim Vallis hypsometric and volume deposits analyses point out that Gusev impact was subsequent to the first incision of Ma'adim Vallis in the craterized upland. The study of the deposit distributions as revealed by the topography leads to reconstruct the chronology of three major events in the Aeolis Region : Ma'adim incision, Gusev impact, and Apollinaris Patera/flow interactions.

SPATIAL VARIATION IN THE SEASONAL SOUTH POLAR CAP OF MARS AS OBSERVED BY MARINER 7 Abstract Only
Wendy M. Calvin, Terry Z. Martin (Jet Propulsion Lab., California Inst. of Tech., Pasadena.), and Gary B. Hansen (Washington Univ., Seattle.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 243-244 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Spatial variations in infrared spectra of the seasonal south polar cap of Mars were noted by the original Mariner 7 IRS instrument team as well as in subsequent examinations of the Mariner 7 data set. Up to now, however, there has been little effort to synthesize this information to understand variations in the south seasonal cap as a function of position or latitude. An attempt to quantify the spectra is made by providing estimates of CO2 grain sizes as well as upper limits on the amount of water frost contained in the polar collar. The variation in brightness at two wavelengths as well as the band depth of a weak CO2-ice feature at 2.28 microns as a function of spectrum number or subsequent location on the cap is presented. The full spectra, corrected only for the solar incidence angle, of three of the most significant areas are compared. Author (revised)

THE GIANT IMPACT PRODUCED A PRECIPITATED MOON Abstract Only c90
A. G. W. Cameron *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 245-246 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The author's current simulations of Giant Impacts on the protoearth show the development of large hot rock vapor atmospheres. The Balbus-Hawley mechanism will pump mass and angular momentum outwards in the equatorial plane; upon cooling and expansion the rock vapor will condense refractory material beyond the Roche distance, where it is available for lunar formation. During the last seven years, the author together with several colleagues has carried out a series of numerical investigations of the Giant Impact theory for the origin of the Moon. These involved three-dimensional simulations of the impact and its aftermath using Smooth Particle Hydrodynamics (SPH), in which the matter in the system is divided into discrete particles whose motions and internal energies are determined as a result of the imposed initial conditions. Densities and pressures are determined from the combined overlaps of the particles, which have a bell-shaped density distribution characterized by a smoothing length. In the original series of runs all particle masses and smoothing lengths had the same values; the matter in the colliding bodies consisted of initial iron cores and rock (dunite) mantles. Each of 41 runs used 3,008 particles, took several weeks of continuous computation, and gave fairly good representations of the ultimate state of the post-collision body or bodies but at best crude and qualitative information about individual particles in orbit. During the last two years an improved SPH program was used in which the masses and smoothing lengths of the particles are variable, and the intent of the current series of computations is to investigate the behavior of the matter exterior to the main parts of the body or bodies subsequent to the collisions. These runs are taking times comparable to a year of continuous computation in each case; they use 10,000 particles with 5,000 particles in the target and 5,000 in the impactor, and the particles thus have variable masses and smoothing lengths (the latter are dynamically adjusted so that a particle typically overlaps a few tens of its neighbors). Since the matter in the impactor provides the majority of the mass left in orbit after the collision, and since the masses of the particles that originated in the impactor are smaller than those in the target, the mass resolution in the exterior parts of the problem is greatly improved and the exterior particles properly simulate atmospheres in hydrostatic equilibrium.

GEOLOGY AND SURFACE CHARACTERISTICS OF BELL REGIO, VENUS Abstract Only

Bruce A. Campbell and Patricia G. Rogers (National Aeronautics and Space Administration, Washington, DC.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 247-248 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Bell Regio is a broad topographic rise located at approximately 30 deg N, 45 deg E which extends approximately 1500 km in the N-S direction and is characterized by extensive volcanism. The geology and surface characteristics of Bell Regio are examined in order to understand the geologic evolution of the region and the surface characteristics of the major volcanic units. Relationships between Magellan SAR backscatter values and altimeter-derived ring slope data are analyzed, and terrestrial SAR data are used to suggest possible surface morphologies.

LAVA FLOWS ON VENUS: ANALYSIS OF MOTION AND COOLING Abstract Only

Bruce A. Campbell and James R. Zimbelman *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 249-250 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Effusive volcanism is a major mechanism for resurfacing on Venus. The large edifice complexes are marked by lava flow fields which extend hundreds of kilometers from their apparent source vents. Earlier work on the emplacement of lava predicted few major differences in flow length between Venus and the Earth (for similar magmas) based primarily on assessment of the relative rates of heat loss to their respective atmospheres. This analysis, combined with the obvious presence of very long lava flows on Venus, has led to suggestions that basalt magmas on Venus may be of generally lower viscosity or that magma effusion rates exceed terrestrial norms. If correct, these hypotheses might imply systematically different chemical and dynamic characteristics for volcanic processes on Venus, and a somewhat catastrophic history for many of the large edifices and flow fields. The mechanics of magma motion and cooling are re-examined, and some of the issues involved in analyzing flows on Venus are discussed.

STRATIGRAPHY AND SEDIMENTOLOGY OF THE K/T BOUNDARY DEPOSIT IN HAITI Abstract Only c46

S. Carey, H. Sigurdsson, S. DHondt, and J. M. Espindola (Universidad Nacional Autonoma de Mexico, Mexico City.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 251-252 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

The K/T boundary sequence is exposed in uplifted carbonate sediments of the southwest peninsula of Haiti. It is found at 15 localities within the Beloc formation, a sequence of limestone and marls interpreted as a monoclinal nappe structure thrust to the north. This tectonic deformation has affected the K/T boundary deposit to varying degrees. In some cases the less competent K/T deposit has acted as a slip plane leading to extensive shearing of the boundary layer, as well as duplication of the section. The presence of glassy tektites, shocked quartz, and an Ir anomaly directly link the deposit to a bolide impact. Stratigraphic and sedimentological features of the tripartite sequence indicate that it was formed by deposition from ballistic fallout of coarse tektites, emplacement of particle gravity flows and fine grained fallout of widely dispersed impact ejecta.

GALILEO/NIMS NEAR-INFRARED THERMAL IMAGERY OF THE SURFACE OF VENUS Abstract Only

R. W. Carlson, K. H. Baines, M. Girard, L. W. Kamp, P. Drossart (Observatoire de Paris-Meudon, France.), T. Encrenaz (Observatoire de Paris-Meudon, France.), and F. W. Taylor (Oxford Univ., England.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 253 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Numerous highland and lowland features on the surface of Venus are observed in multispectral imagery acquired at approximately 50 km spatial resolution by the Near-Infrared Mapping Spectrometer (NIMS) on board the Galileo spacecraft in Feb. 1990. Specifically, such features are observed at 1.18 microns, a wavelength particularly sensitive to thermal emission from the hot, lower atmosphere (less than 10 km) and surface, and show up particularly well when this image is 'de-clouded' using a simultaneously-acquired 2.3-microns image of the upper, cloudy atmosphere. Due to the steep atmospheric temperature gradient (approximately 8 degrees per kilometer), hot lowland areas appear relatively bright, while cooler, highland areas appear dark (due to the steep atmospheric temperature gradient - approximately 8 degrees per kilometer - surface temperatures span approximately 100 K over the 13 kilometer range of surface altitudes observed in this image). Prominent highland features include Maxwell Montes (approximately 12 km altitude), Alpha Regio (2.5 km), Eistla Regio (approximately 2.0 km), Bell Regio (2-3 km), and the western edge of Aphrodite Terra (2-2.5 km). Low-lying regions include Sedna Planitia (-1.0 km), Tinatin Planitia (-0.5 km), and the Bereghinya Planitia (0 km). From correlations with radar altimetry maps, such imagery may place useful constraints on surface emissivity and temperature variations, as well as on the nature of continuum opacity of CO2 in the 1-micron region.

PRELIMINARY REPORT OF LUNAR OBSERVATIONS BY THE NEAR-INFRARED MAPPING SPECTROMETER (NIMS) DURING THE SECOND GALILEO EARTH-MOON ENCOUNTER Abstract Only c89

R. W. Carlson, H. H. Kieffer (Geological Survey, Flagstaff, AZ.), K. H. Baines, K. J. Becker (Geological Survey, Flagstaff, AZ.), G. E. Danielson (California Inst. of Tech., Pasadena.), K. Edwards (Geological Survey, Flagstaff, AZ.), F. P. Fanale (Hawaii Univ., Honolulu.), J. Forsythe (SETS Technology, Inc., Mililani, HI.), L. R. Gaddis (Geological Survey, Flagstaff, AZ.), and J. C. Granahan (Hawaii Univ., Honolulu.) et al *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 255-256 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

The Galileo encounter with the Earth-Moon system on 8 Dec. 1992, provided a unique opportunity to observe the Moon. Galileo's closest approach to the Moon was at an altitude of about 110,000 km above an area at about latitude 60N, longitude 60E. During the 12 hours surrounding the time of lunar closest approach, 12 observational sequences were executed by the near-infrared mapping spectrometer (NIMS), many in coordination with other Galileo instruments. These NIMS observations provided nearly complete coverage of the illuminated crescent from phase angles of 123 deg to 14 deg. This phase-angle coverage with nearly constant illumination is not possible from Earth; it is expected to provide substantial new information on the nature of the lunar photometric function over wavelength. As of Jan. 1993, most of the analysis has focused on the highest resolution data (55 km/pixel).

METAL-RICH METEORITES FROM THE AUBRITE PARENT BODY Abstract Only c90

I. Casanova, T. J. McCoy (Hawaii Univ., Hilo.), and K. Keil (Hawaii Univ., Hilo.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 259-260 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Three metal-rich meteorites - Mt. Egerton, Horse Creek, and LEW 88055 - were studied and it is suggested that they formed in the aubrite parent body. LEW 85369 and 88631 may also have a common origin, but these rocks have not yet been studied in detail. This body was probably heated to about 1600 C by a very strong heat source. While molten, metal agglomerated into sizeable nodules which never segregated efficiently to form a core, but were trapped in the silicate mantle. Different clasts and lithologies in aubrites solidified and cooled under local equilibrium conditions of oxygen fugacity, and with different thermal histories. Impacts mixed clasts from throughout the parent body, creating the typical aubrite breccias. Author (revised)

WHY CONVECTIVE HEAT TRANSPORT IN THE SOLAR NEBULA WAS INEFFICIENT Abstract Only c92

P. Cassen *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 261-262 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

The radial distributions of the effective temperatures of circumstellar disks associated with pre-main sequence (T Tauri) stars are relatively well-constrained by ground-based and spacecraft infrared photometry and radio continuum observations. If the mechanisms by which energy is transported vertically in the disks are understood, these data can be used to constrain models of the thermal structure and evolution of solar nebula. Several studies of the evolution of the solar nebula have included the calculation of the vertical transport of heat by convection. Such calculations rely on a mixing length theory of transport and some assumption regarding the vertical distribution of internal dissipation. In all cases, the results of these calculations indicate that transport by radiation dominates that by convection, even when the nebula is convectively unstable. A simple argument that demonstrates the generality (and limits) of this result, regardless of the details of mixing length theory or the precise distribution of internal heating is presented. It is based on the idea that the radiative gradient in an optically thick nebula generally does not greatly exceed the adiabatic gradient. Author (revised)

FAULT GEOMETRIES AND EXTENSION IN THE VALLES MARINERIS, MARS Abstract Only

D. J. Chadwick and B. K. Lucchitta *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 263-264 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

The central troughs of the Valles Marineris system on Mars are generally regarded to be of tectonic origin because they are linear and bounded by faults. Their radial orientation to the Tharsis rise suggests that at least their incipient formation was influenced by the formation of the rise, but the exact role of Tharsis is not yet well understood. Collapse and erosion may have significantly modified the original tectonic troughs. To better understand the magnitude and mechanism of crustal extension across the Valles Marineris, the attitudes of trough-wall faults that parallel the long axes of the troughs were studied. Our results will help to determine if the extension is related to the Tharsis rise, to a local arch along which the troughs lie, or to other mechanisms. Fault-plane attitudes were obtained by performing a photogrammetric study of fault traces in the walls of Candor and Melas Chasmata. If the exposed wall faults are not major trough-bounding faults, it is assumed that these major faults are buried at the base of the walls and have similar geometries to the exposed faults. Three dimensional coordinates of several points along each fault trace were obtained and three-point solutions to their geometries were constructed. As expected, the results show that the faults dip toward the interior of the troughs, suggesting that they are indeed normal faults associated with trough formation. Author (revised)

A TWO-STAGE (TURBULENT-DRAINAGE) MECHANISM FOR THE EMPLACEMENT OF IMPACT CRATER OUTFLOWS ON VENUS Abstract Only

D. J. Chadwick and G. G. Schaber *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 265-266 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Several emplacement mechanisms were proposed for the unique flow features associated with 402 of the 912 impact craters found on Venus to date. Studies based on rheological models and laboratory results have suggested two separate depositional flow mechanisms: a turbulent emplacement and a lava like emplacement. Schultz proposed a progressive transition from the turbulent to the lava like mechanism during deceleration of some turbulent flows. He suggested that these composite flows were emplaced prior to the deposition of the normal ejecta. After an examination of the geomorphologic, stratigraphic, and topographic relations of the flows associated with the 402 craters, it is suggested that most of the outflows result from a two-stage emplacement process. In the first stage, a turbulent, proximal part is usually emplaced downrange of the impact site after the other ejecta materials. In the second stage, a distal part, composed of low-viscosity melt, slowly drains via dendritic channels from the proximal deposit and flows like lava. A few flows were identified that appear to have been emplaced prior to the ejecta; these flows likely result from a different mechanism. Author (revised)

OXYGEN ISOTOPES AS TRACERS OF TEKTITE SOURCE ROCKS: AN EXAMPLE FROM THE IVORY COAST TEKTITES AND LAKE BOSUMTWI CRATER Abstract Only c90

Joel D. Blum, Christian Koeberl (Wien Univ., Austria.), and C. Page Chamberlain *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 267-268 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Oxygen isotope studies of tektites and impact glasses provide an important tool to help in identifying the target lithologies for terrestrial impacts, including the K-T boundary impact. However, such studies may be complicated by modification of the original oxygen isotope values of some source rocks during the tektite formation process either by vapor fractionation or incorporation of meteoric water. To further investigate the relationship between the oxygen isotopic composition of tektites and their source rocks, Ivory Coast tektites and samples of impact glasses and bedrock lithologies from the Bosumtwi Crater in Ghana--which is widely believed to be the source crater for the Ivory Coast tektites--were studied. Our preliminary results suggest that the phyllites and metagraywackes from the Bosumtwi Crater were the predominant source materials for the impact glasses and tektites and that no significant oxygen isotope modification (less than 1 percent delta(O-18)) took place during impact melting. This contrasts with previous studies of moldavites and Australasian tektites and their sedimentary source materials which suggests a 4 to 5 percent lowering of delta(O-18) due to meteoric water incorporation during impact melting. CRATERING ON GASPRA Abstract Only
Clark R. Chapman, Gerhard Neukum (Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Oberpfaffenhofen, Germany.), Joseph Veverka (Cornell Univ., Ithaca, NY.), and Michael Belton (Kitt Peak National Observatory, Tucson, AZ.) *In its* Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 269-270 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The October 1991 Galileo flyby of Gaspra shows that its crater population is dominated by fresh craters several hundred meters in diameter and smaller. They appear to represent a production population because the spatial density is relatively low (few overlaps) and because fresh craters are very abundant; equilibrium could be attained at diameters near to or below the resolution limit of the best image. These craters are the first direct record of the population of main-belt asteroids some tens of meters in diameter. Craters primarily from the highest resolution, 'high phase' image, on which over 600 craters are visible in 90 sq. km were counted, measured, and classified; earlier counts were made on the lower resolution four-color images, which show an order of magnitude fewer craters because of the resolution limit. The population index (exponent of the differential power law approximately describing the crater sizes) has a very high negative value (-4.3 +/- 0.3, meaning that the log-log slope is 'steep'), appreciably steeper than the value of -3.5 thought to reflect collisional equilibrium according to theory. SHOCK INDUCED REACTION IN CHICXULUB TARGET MATERIALS (CaSO4 AND SIO2) AND THEIR RELATION TO EXTINCTIONS Abstract Only **c46**
Guangqing Chen and Thomas J. Ahrens *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 273-274 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The global platinum element rich layer, the presence of shocked quartz grains (in some cases with stishovite), and the observation of a tektite-rich layer, precisely at the K-T boundary, are the three major arguments for the extinction bolide impact hypothesis of Alvarez et al. Tektites (spherules) from Beloc in Haiti and Mimbral in Mexico received particular interest because of their geological proximity to the Chicxulub impact structure, which is a leading candidate for at least one of the K-T impact craters. Although in most localities the original glass has weathered to clay minerals, some shock-induced glass is found in outcrops and drill cores which is used for Ar-38/Ar-39 dating. The glassy tektites were found to be chemically similar and coeval at 65.0 Ma with Chicxulub melt rock. Two kinds of K-T spherules were discovered: (1) a silic black glass; and (2) a yellow glass, enriched in Ca, Mg, and S. The high sulfur content of the glass and the abundance of anhydrite (CaSO4) in the carbonate-evaporite sequence observed in Drill Holes Y-1 and Y-2 at Chicxulub prompted studies of calcium sulfate devolatization. Further discussion of our experiments is presented. Author (revised)

LEW88516 AND SNC METEORITES Abstract Only **c90**
J. H. Chen and G. J. Wasserburg *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 275-276 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

We report on the isotopic composition of Pb and the concentration of Pb, U, and Th in a sample of LEW88516 (LEW). LEW was a 13-g stone recovered from Antarctica and was classified as a new member of the Shergottite group. This work was undertaken with the hope that LEW might yield new information to elucidate further the origin and evolution of Shergottites and other SNC meteorites. We have previously studied U-Th-Pb in other Shergottites, namely Shergotty, Zagami, EETA79001, and ALHA77005, as well as Nakhla. The results indicate that the initial leads of these Shergottites were well defined, were distinct from each other, and have high Pb-204/Pb-206 (from 0.0652 to 0.0739). These leads evolved in different reservoirs over most of solar system history in a low U-238/Pb-204(micro) is approximately equal to 5 environment. The U-Th-Pb isotopic systems are quite regular, which unambiguously indicates an event of U-Th-Pb fractionation at approximately 200 m.y. The details of the data arrays are complex. The young age is in general agreement with some of the ages obtained by other methods, but precise concordance between the different methods is not established. The new results on LEW are remarkably similar to those of ALHA77005 and support the other observations based on the mineralogy, petrology, and bulk composition. The clear distinction between the Shergottites and Nakhla is confirmed. We consider that the Shergottites and possibly all the SNC's were derived from an impact on the regolith of a differentiated terrestrial type planetary body (Mars?) with a high content of volatiles as compared to the earth. THE Th AND U ABUNDANCES IN CHONDRITIC METEORITES Abstract Only **c90**
J. H. Chen, G. J. Wasserburg, and D. A. Papanastassiou *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 277-278 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

We present new analyses of Th-232/U-238 in CI and CM meteorites. The relative abundance of these nuclides is important in estimates of the age of r-process elements. The cosmochronology based upon the Th-232/U-238 ratio (kappa) depends on the precise determinations of these two different elements in meteorites and on the production ratios. Both parameters are subject to substantial errors. Recent recalculations of this chronology have used selected values from compilations but do not adequately address the errors in terms of a reliable data base. Morgan and Lovering provided extensive neutron activation analyses for ordinary chondrites which yield an average kappa of 3.6 +/- 0.4. Their work on carbonaceous chondrites showed a wide range in kappa from 2 to 6. More recent investigations by isotopic dilution have established the following: (1) highly variable kappa from 2.7 to 11 in Allende Ca-Al-rich inclusions and a value of 3.6 in the Orgueil CI1 chondrite; (2) a range from 2.71 to 6.63 for 7 L-type chondrites and a range from 2.7 to 4.4 for 6 L, H, and LL chondrites. A further investigation of this subject matter is presented. Author (revised)

LUNAR SCOUT TWO SPACECRAFT GRAVITY EXPERIMENT Abstract Only
Andrew F. Cheng *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 279 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Measurement of the gravity field of the Moon has a high science priority because of its implications for the internal structure and thermal history of the Moon, and it has a high priority for future exploration activities because of the influence of lunar gravity on spacecraft navigation and orbit maintenance. The current state of knowledge in the lunar gravity field (and the uncertainty in the knowledge) is based primarily on data accumulated from the Lunar Orbiter and Apollo programs. Data are sparse and emphasize the equatorial band (+/- 30 deg) on the near side of the Moon. There are no tracking data on the far side and only the Lunar Orbiter 5 provides a small amount of high inclination data. A host of gravity models developed from different combinations of tracking data have large discrepancies in their predictions of spacecraft motion and orbit lifetimes. There are also large disagreements in the Mercator projections of the gravity acceleration from each model, especially on the far side, where the contours tend to have no obvious relationship with the local topography. The science and engineering requirements for global gravity field mapping will be satisfied with continuous radio metric tracking of Lunar Scout 1 in a low polar orbit using the Deep Space Network and Lunar Scout 2 in a high elliptical orbit. The gravity field of the Moon will be mapped during the Scout Program using a two spacecraft concept. In the two spacecraft concept, one spacecraft is placed in a high altitude eccentric orbit while the second spacecraft is in a low altitude polar orbit. The gravity experiment requires a radio frequency that will permit two-way Doppler tracking between the spacecraft and the Deep Space Network (DSN). Both spacecraft carry NASA standard transponder systems for data transmission to Earth as well as for tracking and orbit determination. Data sufficient to produce a gravity field map could be acquired within one month with this system. Author (revised)

MISSION TO THE MOON: AN ESA STUDY ON FUTURE EXPLORATION Abstract Only
A. F. Chicarro *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 281-282 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The increasing worldwide interest in the continuation of lunar exploration has convinced ESA to carry out an investigation of the motivations to return to the Moon to establish a permanent or a semi-permanent manned lunar base. This study also considers the possible role Europe could play in the future exploration and possible utilization of the Moon. The study concentrated in this first phase mainly on scientific questions, leaving technological issues such as transportation, the role of humans, infrastructure, and policy matters to a later phase. It only partially considered questions relating to the exploitation of lunar resources and the impact of human activities on science. Author (revised)

FRACTAL DIMENSIONS OF RAMPART IMPACT CRATERS ON MARS Abstract Only
Delwyn Ching, G. Jeffrey Taylor, Peter Mouginis-Mark, and Barbara C. Bruno *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 283-284 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Ejecta blanket morphologies of Martian rampart craters may yield important clues to the atmospheric densities during impact, and the nature of target materials (e.g., hard rock, fine-grained sediments, presence of volatiles). In general, the morphologies of such craters suggest emplacement by a fluidized, ground hugging flow instead of ballistic emplacement by dry ejecta. We have quantitatively characterized the shape of the margins of the ejecta blankets of 15 rampart craters using fractal geometry. Our preliminary results suggest that the craters are fractals and are self-similar over scales of approximately 0.1 km to 30 km. Fractal dimensions (a measure of the extent to which a line fills a plane) range from 1.06 to 1.31. No correlations of fractal dimension with target type, elevation, or crater size were observed, though the data base is small. The range in fractal dimension and lack of correlation may be due to a complex interplay of target properties (grain size, volatile content), atmospheric pressure, and crater size. The mere fact that the ejecta margins are fractals, however, indicates that viscosity and yield strength of the ejecta were at least as low as those of basalts, because silicic lava flows are not generally fractals. A SIMPLE MODEL OF CLASTIC SEDIMENTS ON MARS Abstract Only
Philip R. Christensen and Michael C. Malin (Malin Space Science Systems, San Diego, CA.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 285-286 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

In preparation for the start of Mars Observer operations at Mars later this year, Viking Infrared Thermal Mapper (IRTM) observations were synthesized into a simple but geologically coherent conceptual model for use in establishing targets for coordinated Thermal Emission Spectrometer (TES) and Mars Observer Camera (MOC) observations. The model is based on three assumptions that are, at best, only partly true: that albedo is a measure of the presence or absence of dust; that thermal inertia is a measure of the weighted average particle size; and that rock abundance is a measure of the statistical thickness of fine sediment (i.e., that the observed areal abundance of rock reflects the whole or partial burial of rocks). Using this model, it is possible to show that, on the scale of 30 km, mantles of wind-transportable sediment (dust and sand) are at most about 1 m thick, and that on a global average such mantles are about 35 cm thick. It is shown that 3.8 x 10(exp 19) cu cm of such sediment covers Mars equatorward of +/- 60 deg latitude. Using the model, interpretation of digital maps of IRTM data focus attention not only on areas where dust is the primary sediment (e.g., Arabia Terra), but also on areas where sand is the primary sediment (e.g., eastern Valles Marineris) and where rocks and other coarse materials are abundant (e.g., eastern Kasei Vallis). Three IRTM data sets are used in the analysis: Viking 1 and 2 pre-dawn observations mosaiced into a global map of single-point thermal inertias at 0.5 deg/bin resolution; Pleskot and Miner's global albedo map using the best available, clear-period IRTM observations (1x/bin); and Christensen's 1 deg/bin rock abundance map. Uncertainty analyses indicate these data sets to be accurate to 5 percent, 2 percent, and 20 percent, respectively. Author (revised)

Thermal-infrared vibrational spectroscopy has great potential for remotely determining the composition of planetary surface materials by taking advantage of fundamental molecular vibrational modes that produce spectral features in the range from approximately 3 to greater than 50 microns. Much of the current interest in the thermal infrared wavelength region stems from the deployment of multispectral scanners, such as the Thermal Infrared Multispectral Scanner (TIMS) and the Mars Observer Thermal Emission Spectrometer (TES). In order to support these missions, it is necessary to develop an appropriate library of laboratory measurements. The purpose of this work was to develop a technique which, with a very limited set of assumptions, can be used to determine the emissivity of natural surfaces directly by using emitted energy. COLLISIONS OF SMALL SPACEWATCH ASTEROIDS WITH THE EARTH Abstract Only **c90**
C. F. Chyba *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 289-290 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The discovery, with the Spacewatch Telescope, of 8 Earth-approaching objects smaller than 100 m in diameter has been reported. I have calculated the probability and velocity of collision with Earth for each of these objects. Using a code we have successfully employed to model the Tunguska and Revelstoke atmospheric explosions, I have simulated the entry of these objects into Earth's atmosphere, assuming iron, stony, carbonaceous, and cometary compositions. The smallest of these objects, with tens to hundreds of kilotons of kinetic energy, pose a substantial threat at the surface only if they are iron objects. An object is taken to 'pose a substantial threat' if it either craters the ground, or explodes in the atmosphere with sufficient energy at low enough altitude to create an overpressure at the surface capable of felling trees or destroying buildings. Larger objects, with energies greater than about a megaton, devastate the surface regardless of whether they are of iron, stony, or carbonaceous composition. Iron objects crater the ground, whereas stony and carbonaceous objects explode in the atmosphere low enough to fell trees and damage buildings over thousands of square kilometers. Spacewatch objects, if presumed to be of carbonaceous composition, are as dangerous as their stony counterparts, as the former objects' lower yield strengths (and hence, higher explosion altitudes) are roughly compensated by their larger masses (as derived from their lower albedos for a given observed magnitude). Although comets are intrinsically less dangerous than asteroids, the 90 m diameter Spacewatch objects would devastate hundreds of square kilometers at the surface, even if cometary. Author (revised)

DIFFERENTIAL SCALING: IMPLICATIONS FOR CENTRAL STRUCTURES IN LARGE LUNAR CRATERS Abstract Only
M. J. Cintala and R. A. F. Grieve (Geological Survey of Canada, Ottawa, Ontario.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 291-292 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The change in morphology of central structures with crater size on the terrestrial planets has been studied by many investigators. While the progression of morphological change essentially follows the same basic pattern, the appearance of central peaks, and the transitions from single to multiple peaks and peaks to peak rings occur at crater diameters that appear to be dependent on parameters associated with the target planet. Statistical data, morphological information, and model results exist for central structures in large craters, but the amount of 'ground truth' is comparatively meager. What, for instance, is the amount of stratigraphic uplift in craters? Answers to questions such as this will provide useful constraints on models of origin for central structures and would help in interpretation of remote-sensing data. This contribution uses terrestrial information and model calculations to estimate the amount of stratigraphic uplift for central-peak craters on the Moon--the only planet other than Earth for which sufficient topographic data are available. IMPACT COMMINUTION OF GLASSES: IMPLICATIONS FOR LUNAR REGOLITH EVOLUTION Abstract Only
Mark J. Cintala, Sheila Smith (Baylor Univ., Waco, TX.), and Friedrich Hoerz *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 293-294 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Glasses are important parts of every lunar regolith sample, whether in the form of indigenous melts such as mesostasis or pyroclastics, or as quenched impact melts. The modal proportions of agglutinitic impact melts alone can exceed 50 percent for some mature regoliths, and glasses are commonly the most dominant single component of lunar soils. They therefore participate in and possibly affect all evolutionary processes to which regoliths are subjected, such as comminution and attendant chemical fractionation as a function of grain size, the retention of solar-wind products, the production of superparamagnetic iron, and others. Because they are such an integral part of lunar regoliths, a more complete understanding of regolith evolution must include the role played by these vitreous components. This contribution examines the comminution behavior of a variety of glasses and a fine-grained basalt under conditions of repetitive impact, and compares this behavior to those of crystalline components, such as lithic fragments and major rock-forming minerals. MICROTEKTITE-LIKE GLASS SPHERULES IN LATE DEVONIAN (367 MA) SHALES Abstract Only
Philippe Claeys and Jean-Georges Casier (Institut Royal des Sciences Naturelles de Belgique, Brussels.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 295-296 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Glass spherules are found closely associated with the Frasnian-Famennain (FF) boundary in two sections, Senzeille and Hony, located in the Dinant basin in the South of Belgium. These spherules are interpreted, based on their chemistry and low water content, as impact produced microtektite-like glass. Craters of Late Devonian ages include the Siljan Ring (Sweden), Charlevoix (Quebec), and Taihu Lake (China). The occurrence of microtektite-like glass closely associated with the FF mass extinction is intriguing. The relationships between the impact and the extinction event deserve further study. Avail: CASI HC A01/MF A06

Cretaceous-Tertiary boundary (KTB) tektite glasses occur at several sites around the Gulf of Mexico. Contrary to rumor among KTB workers, glass fragments have been found by several researchers in the base of the spherule bed at Arroyo el Mimbral in NE Mexico. The presence of green, red, and transparent glass fragments at Mimbral only, demonstrates that the Mimbral glass is not a laboratory contamination by Beloc glass. The chemistry and ages of the glass are consistent with an origin from the Chixculub impact crater in Yucatan. No evidence supports a volcanic origin for the KTB glasses. A discussion of tektite glass from the KT boundary is presented. Author (revised)

FIRST RESULTS OF THE SEVEN-COLOR ASTEROID SURVEY Abstract Only **c90**
Beth E. Clark, Jeffrey F. Bell, Fraser P. Fanale, and Paul G. Lucey *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 299-300 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The new Seven-Color infrared filter system (SCAS), designed specifically to capture the essential mineralogical information present in asteroid spectra, is composed of seven broad-band filters which allow for IR observations of objects as faint as 17th magnitude. The first test of the SCAS system occurred in Jul. 1992. In four nights at the IRTF on Mauna Kea, Hawaii, over 67 objects were observed. Five of the observations were to test the new system for accuracy relative to previous observations with the high-resolution 52 Color Infrared Survey and with the Eight-Color Asteroid Survey (ECAS). In three cases, the match with previous data was good. In two cases, the match to previous observations was not as good. In addition, sixty S-Type asteroids were measured with the SCAS system. Forty of those asteroids were also observed with the ECAS system. Among the new observations is infrared data of 371 Bohemia, a main belt asteroid which was classified 'QSV' according to its UBV colors in the taxonomic system of D.J. Tholen. There are no corresponding ECAS data for 371. Q-type asteroids are of special interest as they are proposed to be the elusive parent bodies of the ordinary chondrite meteorites. Most Q-types are Earth-crossing asteroids and have not yet been observed in the infrared (except, perhaps, 371). Positive identification of a large main belt Q-type would be of major importance in the scheme of the geological structure of the asteroid belt. Without visible wavelength data, however, the classification of 371 Bohemia remains ambiguous. An attempt to conjoin Bohemia SCAS data with ECAS data of both a typical Q-Type asteroid and an average S-Type asteroid is shown. This figure thus illustrates the importance of visible wavelength data to the SCAS system. In other words, without ECAS data of 371 Bohemia we cannot use its spectral characteristics to identify it as a possible parent body of ordinary chondrite meteorites. Author (revised)

SIMULATION OF POSSIBLE REGOLITH OPTICAL ALTERATION EFFECTS ON CARBONACEOUS CHONDRITE METEORITES Abstract Only c90
Beth E. Clark, Fraser P. Fanale, and Mark S. Robinson *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 301-302 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

As the spectral reflectance search continues for links between meteorites and their parent body asteroids, the effects of optical surface alteration processes need to be considered. We present the results of an experimental simulation of the melting and recrystallization that occurs to a carbonaceous chondrite meteorite regolith powder upon heating. As done for the ordinary chondrite meteorites, we show the effects of possible parent-body regolith alteration processes on reflectance spectra of carbonaceous chondrites (CC's). For this study, six CC's of different mineralogical classes were obtained from the Antarctic Meteorite Collection: two CM meteorites, two CO meteorites, one CK, and one CV. Each sample was ground with a ceramic mortar and pestle to powders with maximum grain sizes of 180 and 90 microns. The reflectance spectra of these powders were measured at RELAB (Brown University) from 0.3 to 2.5 microns. Following comminution, the 90 micron grain size was melted in a nitrogen controlled-atmosphere fusion furnace at an approximate temperature of 1700 C. The fused sample was immediately held above a flow of nitrogen at 0 C for quenching. Following melting and recrystallization, the samples were reground to powders, and the reflectance spectra were remeasured. The effects on spectral reflectance for a sample of the CM carbonaceous chondrite called Murchison are shown. Author (revised)

SPECTRAL MIXING MODELS OF S-TYPE ASTEROIDS Abstract Only c90
Beth E. Clark, Paul G. Lucey, Jeffrey F. Bell, and Fraser P. Fanale *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 303-304 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

This paper presents the results of an attempt to determine S-Type asteroid mineralogies with the use of Hapke theory spectral mixing modelling. Previous attempts to understand the spectral variations present in this single class of asteroids have concentrated on spectral parameters such as absorption band center wavelengths, band area ratios, and geometric albedos. The procedure taken here is to utilize the Hapke spectral reflectance model to calculate single scatter albedo as a function of wavelength for a suite of candidate end-member materials. These materials are then mixed linearly in single scatter albedo space, and the mixture is converted, assuming intimate particle mixing, back to reflectance for the spectrum matching routine. A total of 39 S-Type asteroids selected from the Bell et al. survey have been matched with mixture model spectra. Author (revised)

REMOTE SENSING X RAY FLUORESCENCE SPECTROMETRY FOR FUTURE LUNAR EXPLORATION MISSIONS Abstract Only
Pamela E. Clark, Larry G. Evans (Computer Sciences Corp., Calverton, MD.), and Jacob I. Trombka (National Aeronautics and Space Administration. Goddard Space Flight Center, Greenbelt, MD.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 305-306 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Measurement of discrete line X-ray emission from space can be used to obtain both qualitative and quantitative elemental surface composition information. Remote orbital X-ray elemental analysis is the measurement of characteristic X-rays following the interaction of solar X-rays with the surface of a given solid body. Thus, X-ray emission from a surface is strongly dependent on the incident solar spectrum as well as on the chemical composition of the surface. In this paper, the relationship between the solar flux and the major lunar element fluorescence and scattered X-ray flux is characterized. A model was developed to calculate lunar surface X-ray fluorescence emission spectra under a variety of solar conditions and, in particular, conditions that might be expected for a Lunar Scout mission proposed for 1995 or 1996. This time period should be during solar minimum. Author (revised)

CARBON AND NITROGEN IN TYPE 2 SUPERNOVA DIAMONDS Abstract Only c90
Donald D. Clayton, Mounib ElEid, and Lawrence E. Brown *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 307-308 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Abundant diamonds found in meteorites seem either to have condensed within supernova interiors during their expansions and coolings or to have been present around those explosions. Either alternative allows implantation of Xe-HL prior to interstellar mixing. A puzzling feature is the near normalcy of the carbon isotopes, considering that the only C-rich matter, the He-burning shell, is pure C-12 in that region. That last fact has caused many to associate supernova carbon with C-12 carbon, so that its SUNOCONS have been anticipated as very C-12-rich. We show that this expectation is misleading because the C-13-rich regions of Type 2's have been largely overlooked in this thinking. We here follow the idea that the diamonds nucleated in the C-12-rich He shell, the only C-rich site for nucleation, but then attached C-13-rich carbon during turbulent encounters with overlying C-13-rich matter. That is, the initial diamonds continued to grow during the same collisional encounters that cause the Xe-HL implantation. Instead of interacting with the small carbon mass having $13/12 = 0.2$ in the upper He zone, however, we have calculated the remnants of the initial H-burning core, which left behind C-13-rich matter as it receded during core hydrogen burning. Howard et al. described why the velocity mixing would be essential to understanding the implantation of both the Xe-H and Xe-L components. Velocity mixing is now known to occur from the X-ray and gamma-ray light curves of supernova 1987A. Using the stellar evolution code developed at Goettingen, we calculated at Clemson the evolution of a grid of massive stars up to the beginning of core He burning. We paid attention to all H-burning reactions throughout the star, to the treatment of both convection and semiconvection, and to the recession of the outer boundary of the convective H-burning core as the star expands toward a larger redder state. This program was to generate a careful map of the CNO isotope distribution as He burning begins. Our result for the 30 solar mass star is shown. Author (revised)

MEASUREMENT OF POLYCYCLIC AROMATIC HYDROCARBON (PAHs) IN INTERPLANETARY DUST PARTICLES Abstract Only c90
S. J. Clemett, C. R. Maechling, R. N. Zare, P. D. Swan (Washington Univ., Saint Louis, MO.), and R. M. Walker (Washington Univ., Saint Louis, MO.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 309-310 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

We report here the first definitive measurements of specific organic molecules (polycyclic aromatic hydrocarbons (PAH's)) in interplanetary dust particles (IDP's). An improved version of the microbeam-two-step laser mass spectrometer was used for the analysis. Two IDP's gave similar mass spectra showing an abundance of PAH's. Control samples, including particles of probable terrestrial origin from the same stratospheric collector, gave either null results or quite different spectra. We conclude that the PAH's are probably indigenous to the IDP's and are not terrestrial contaminants. The instrument used to study the particles is a two-step laser mass spectrometer. Constituent neutral molecules of the sample are first desorbed with a pulsed infrared laser beam focussed to 40 micrometers. In the second step, PAH's in the desorbed plume are preferentially ionized by a pulsed UV laser beam. Resulting ions produced by resonant absorption are extracted into a reflectron time-of-flight mass spectrometer. This instrument has high spatial resolution, high ion transmission, unlimited mass range, and multichannel detection of all ion masses from a single laser shot. Author (revised)

MARS: THE INITIAL EMPLACEMENT OF GROUND ICE IN RESPONSE TO THE THERMAL EVOLUTION OF ITS EARLY CRUST Abstract Only
Stephen M. Clifford *In its* Twenty-fourth Lunar and Planetary Science

Conference. Part 1: A-F 1993 p 311-312 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Given the geomorphic evidence for the widespread occurrence of water and ice in the early martian crust, and the difficulty involved in accounting for this distribution given the present climate, it has been suggested that the planet's early climate was originally more Earth-like, permitting the global emplacement of crustal H2O by direct precipitation as snow or rain. The resemblance of the martian valley networks to terrestrial runoff channels, and their almost exclusive occurrence in the planet's ancient (approximately 4 billion year old) heavily cratered terrain, is often cited as evidence of just such a period. An alternative school of thought suggests that the early climate did not differ substantially from that of today. Advocates of this view find no compelling reason to invoke a warmer, wetter period to explain the origin of the valley networks. Rather, they cite evidence that the primary mechanism of valley formation was ground water sapping, a process that does not require that surface water exist in equilibrium with the atmosphere. However, while sapping may successfully explain the origin of the small valleys, it fails to address how the crust was initially charged with ice as the climate evolved towards its present state. Therefore, given the uncertainty regarding the environmental conditions that prevailed on early Mars, the initial emplacement of ground ice is considered from two perspectives: (1) that the early climate started warm and wet, but gradually cooled with time; and (2) that it never differed substantially from that of today. Author (revised)

THE ROLE OF THE GEOTHERMAL GRADIENT IN THE EMPLACEMENT AND REPLENISHMENT OF GROUND ICE ON MARS Abstract Only
Stephen M. Clifford *In its* Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 313-314 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Knowledge of the mechanisms by which ground ice is emplaced, removed, and potentially replenished, are critical to understanding the climatic and hydrologic behavior of water on Mars, as well as the morphologic evolution of its surface. Because of the strong temperature dependence of the saturated vapor pressure of H2O, the atmospheric emplacement or replenishment of ground ice is prohibited below the depth at which crustal temperatures begin to monotonically increase due to geothermal heating. In contrast, the emplacement and replenishment of ground ice from reservoirs of H2O residing deep within the crust can occur by at least three different thermally-driven processes, involving all three phases of water. In this regard, Clifford has discussed how the presence of a geothermal gradient as small as 15 K/km can give rise to a corresponding vapor pressure gradient sufficient to drive the vertical transport of 1 km of water from a reservoir of ground water at depth to the base of the cryosphere every 10(exp 6) - 10(exp 7) years. This abstract expands on this earlier treatment by considering the influence of thermal gradients on the transport of H2O at temperatures below the freezing point. Author (revised)

THE THERMODYNAMIC CASE FOR A WATER-RICH MARS Abstract Only
Stephen M. Clifford *In its* Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 315-316 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The geologic evidence for a water-rich Mars has been reviewed, and it has been concluded that it is consistent with an outgassed inventory of H2O equivalent to global ocean 0.5-1 km deep. The most persuasive support for this conclusion comes from the martian outflow channels, whose distribution, size, and range of ages, suggests that a significant body of ground water was present on Mars throughout much of its geologic history. In this abstract, the thermodynamic implications of the outflow channels are considered. The results of this analysis suggest that if the outflow channels were carved by the discharge of ground water in diffusive and thermodynamic equilibrium with the overlying frozen crust, it implies a minimum planetary inventory of water in excess of 300 m. However, if the global inventory of ground water on Mars at the time of outflow channel formation was as high as the 500 m estimate of other researchers, then the total inventory of water on Mars could well exceed 750 m.

REMANENT MAGNETISM OF HED METEORITES: IMPLICATIONS FOR THEIR EVOLUTION AND ANCIENT MAGNETIC FIELDS Abstract Only c90
D. W. Collinson and S. J. Morden *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 319-320 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The magnetic properties of extraterrestrial materials, in particular natural remanent magnetization (NRM), is a potentially useful study for detecting ancient Solar System magnetic fields and for elucidating meteorite evolutionary processes. Results are presented for the following: howardites--Kapoeta, Petersburg, Le Teilleul, and EET 87503; eucrites--Sioux County and Millbillillie; and diogenites--Shalka and Johnstown. Significant features of their magnetism are within-sample in homogeneity of NRM directions in several of the meteorites and within-sample uniformity of axes of an isotropy of magnetic susceptibility. Both these phenomena bear on the meteorites' evolution and the timing of the magnetization process.

GRAPHITE SOLUBILITY AND CO-VESICULATION IN BASALT-LIKE MELTS AT ONE-ATM Abstract Only
R. O. Colson *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 321-322 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The identity and source of the vapor phase that caused lunar lava-fountaining and vesiculation in lunar basalts continues to be of interest because of its implications for the composition and state of the lunar interior and because of its implications for lunar resources. In light of the apparent near-absence of H2O on the Moon, it has been suggested that the vapor phase may be CO2-CO. This premise is supported by the presence of carbon on the surface of volcanic glass beads. However, although the rapid exsolution of CO2 from a melt during decompression may be consistent with firefountaining, it fails to provide a satisfying explanation for vesiculation in mare basalt where exsolution of the gas phase would more reasonably be related to cooling/crystallization at low pressure rather than decompression from high pressure. Also, geochemical trends in lunar volcanic glasses suggest that their source has an oxygen fugacity more reducing than the iron-wustite buffer, an oxygen fugacity that is inconsistent with presence of dissolved CO2-CO at depth. The results of experiments in which a vesicular 'basalt' is produced from a melt equilibrated with graphite and pure CO gas at one atmosphere pressure are reported. The vesiculation is apparently related to exsolution of CO or a CO species during cooling of the melt or growth of quench crystals. Additionally, particulate carbon dispersed through the quenched sample suggests that elemental carbon is either in solution in the melt prior to quenching or tends to go into suspension perhaps as colloid-like particles. These two observations may provide insight into the nature of fire-fountaining and vesiculation on the Moon. Author (revised)

CRYSTAL-CHEMISTRY AND PARTITIONING OF REE IN WHITLOCKITE Abstract Only **c76**
R. O. Colson and B. L. Jolliff *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 323-324 (For primary document see N94-12015 01-91)
(Grant NAG9-56)
Avail: CASI HC A01/MF A06

Partitioning of Rare Earth Elements (REE) in whitlockite is complicated by the fact that two or more charge-balancing substitutions are involved and by the fact that concentrations of REE in natural whitlockites are sufficiently high such that simple partition coefficients are not expected to be constant even if mixing in the system is completely ideal. The present study combines preexisting REE partitioning data in whitlockites with new experiments in the same compositional system and at the same temperature (approximately 1030 C) to place additional constraints on the complex variations of REE partition coefficients and to test theoretical models for how REE partitioning should vary with REE concentration and other compositional variables. With this data set, and by combining crystallographic and thermochemical constraints with a SAS simultaneous-equation best-fitting routine, it is possible to infer answers to the following questions: what is the speciation on the individual sites Ca(B), Mg, and Ca(IIA) (where the ideal structural formula is Ca(B)18 Mg2Ca(IIA)2P14O56); how are REE's charge-balanced in the crystal; and is mixing of REE in whitlockite ideal or non-ideal. This understanding is necessary in order to extrapolate derived partition coefficients to other compositional systems and provides a broadened understanding of the crystal chemistry of whitlockite. POWER-LAW CONFUSION: YOU SAY INCREMENTAL, I SAY DIFFERENTIAL Abstract Only **c65**
Joshua E. Colwell *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 325-326 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Power-law distributions are commonly used to describe the frequency of occurrences of crater diameters, stellar masses, ring particle sizes, planetesimal sizes, and meteoroid masses to name a few. The distributions are simple, and this simplicity has led to a number of misstatements in the literature about the kind of power-law that is being used: differential, cumulative, or incremental. Although differential and cumulative power-laws are mathematically trivial, it is a hybrid incremental distribution that is often used and the relationship between the incremental distribution and the differential or cumulative distributions is not trivial. In many cases the slope of an incremental power-law will be nearly identical to the slope of the cumulative power-law of the same distribution, not the differential slope. The discussion that follows argues for a consistent usage of these terms and against the oft-made implicit claim that incremental and differential distributions are indistinguishable. THE EXPERIMENTAL PRODUCTION OF MATRIX LUMPS WITHIN CHONDRULES: EVIDENCE OF POST-FORMATIONAL PROCESSES Abstract Only **c90**
Harold C. Connolly, Jr. and Roger H. Hewins *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 327-328 (For primary document see N94-12015 01-91)
(Grant NGT-50836)
Avail: CASI HC A01/MF A06

The processes that acted upon chondrules after their formation are as important clues to the nature of the early solar nebula as are the exact processes that formed the chondrules. Recent experiments have studied the rim forming processes and the effects the processes have on chondrules. We present below information on how matrix inclusions found within chondrules may have been formed and the potential usefulness of this information. Author (revised)

FLASH MELTING OF CHONDRULE PRECURSORS IN EXCESS OF 1600 C. SERIES 1: TYPE 2 (B1) CHONDRULE COMPOSITION EXPERIMENTS Abstract Only **c90**
Harold C. Connolly, Jr., Roger H. Hewins, and Gary E. Lofgren (National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, TX.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 329-330 (For primary document see N94-12015 01-91)
(Grant NGT-50836)
Avail: CASI HC A01/MF A06

Several questions in chondrule production remain an enigma despite years of experiments. What were the melting temperatures experienced by chondrules? What were the physical characteristics of chondrule precursors? How and why did volatile elements (i.e. Na) found within chondrules survive the formation process? We present the initial results of a series of experiments designed to investigate the above questions by using flash melting to duplicate the melting stage of chondrule formation. Author

Avail: CASI HC A01/MF A06

Realizing and understanding the effects of the near-Earth space environment on a spacecraft during its mission lifetime is becoming more important with the regeneration of America's space program. Included among these potential effects are the following: erosion and surface degradation due to atomic oxygen impingement; ultraviolet exposure embrittlement; and delamination, pitting, cratering, and ring formation due to micrometeoroid and debris impacts. These effects may occur synergistically and may alter the spacecraft materials enough to modify the resultant crater, star crack, and/or perforation. This study concentrates on modelling the effects of micrometeoroid and debris hypervelocity impacts into aluminum materials (6061-T6). Space debris exists in all sizes, and has the possibility of growing into a potentially catastrophic problem, particularly since self-collisions between particles can rapidly escalate the number of small impactors. We have examined the morphologies of the Long Duration Exposure Facility (LDEF) impact craters and the relationship between the observed impact damage on LDEF versus the existing models for both the natural (micrometeoroid) and manmade (debris) environments in order to better define these environments. USING LUNAR SOUNDER IMAGERY TO DISTINGUISH SURFACE FROM SUBSURFACE REFLECTORS IN LUNAR HIGHLANDS AREAS Abstract Only
Bonnie L. Cooper and James L. Carter (Texas Univ., Dallas.) *In its* Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 333-334 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

We have developed a method using the Apollo 17 Lunar Sounder imagery data which appears capable of filtering out off-nadir surface noise from highland area profiles, so that subsurface features may now be detected in highland areas as well as mare areas. Previously, this had been impossible because the rough topography in the highland areas created noise in the profiles which could not be distinguished from subsurface echoes. The new method is an image processing procedure involving the computerized selection of pixels which represent intermediate echo intensity values, then manually removing those pixels from the profile. Using this technique, a subsurface feature with a horizontal extent of about 150 km, at a calculated depth of approximately 3 km, has been detected beneath the crater Riccioli in the highlands near Oceanus Procellarum. This result shows that the ALSE data contain much useful information that remains to be extracted and used. Author (revised)

GEOLOGIC HISTORY OF CENTRAL CHRYSE PLANITIA AND THE VIKING 1 LANDING SITE, MARS Abstract Only

Robert A. Craddock, L. S. Crumpler (Brown Univ., Providence, RI.), and Jayne C. Aubele (Brown Univ., Providence, RI.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 335-336 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

A 1:500,000 scale geologic mapping was undertaken to synthesize the broad-scale geology of Chryse Planitia with the local geology of the Viking 1 landing site. The geology of Mars Transverse Mercators (MTM's) 20047 and 25047 has been presented previously. As part of the goals for the Mars Geologic Mapping program, the rational and scientific objectives for a return mission to Chryse Planitia and the Viking 1 Lander have also been presented. However, in mapping central Chryse Planitia our principle objective was to determine the depositional and erosional history of the Chryse Planitia basin. These results are presented. MACROSCOPIC ELECTRIC CHARGE SEPARATION DURING HYPERVELOCITY IMPACTS: POTENTIAL IMPLICATIONS FOR PLANETARY PALEOMAGNETISM Abstract Only c90

D. A. Crawford and P. H. Schultz *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 337-338 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

The production of transient magnetic fields by hypervelocity meteoroid impact has been proposed to possibly explain the presence of paleomagnetic fields in certain lunar samples as well as across broader areas of the lunar surface. In an effort to understand the lunar magnetic record, continued experiments at the NASA Ames Vertical Gun Range allow characterizing magnetic fields produced by the 5 km/s impacts of 0.32-0.64 cm projectiles over a broad range of impact angles and projectile/target compositions. From such studies, another phenomenon has emerged, macroscopic electric charge separation, that may have importance for the magnetic state of solid-body surfaces. This phenomenon was observed during explosive cratering experiments, but the magnetic consequences of macroscopic electric charge separation (as opposed to plasma production) during explosion and impact cratering have not, to our knowledge, been explored before now. It is straightforward to show that magnetic field production due to this process may scale as a weakly increasing function of impactor kinetic energy, although more work is needed to precisely assess the scaling dependence. The original intent of our experiments was to assess the character of purely electrostatic signals for comparison with inferred electrostatic noise signals acquired by shielded magnetic sensors buried within particulate dolomite targets. The results demonstrated that electrostatic noise does affect the magnetic sensors but only at relatively short distances (less than 4 cm) from the impact point (our magnetic studies are generally performed at distances greater than approximately 5.5 cm). However, to assess models for magnetic field generation during impact, measurements are needed of the magnetic field as close to the impact point as possible; hence, work with an improved magnetic sensor design is in progress. In this paper, we focus on electric charge separation during hypervelocity impacts as a potential transient magnetic field production mechanism in its own right. Author (revised)

RHENIUM-OSMIUM ISOTOPE SYSTEMATICS OF GROUP 2A AND GROUP 4A IRON METEORITES Abstract Only c90

R. A. Creaser (Alberta Univ., Edmonton.), D. A. Papanastassiou, and G. J. Wasserburg *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 339-340 (For primary document see N94-12015 01-91)

(Grant NAG9-43)

Avail: CASI HC A01/MF A06

We are investigating the Re-Os isotope systematics of two groups of magmatic iron meteorites (2A, 4A) in an attempt to establish precise 'total rock' isochrons by the Re-Os system. The Re-187/Os-187 isotope system is recognized as a method by which the ages of iron meteorites can be directly determined and that can provide information on the timing of FeNi segregation and core formation in planetesimals. The Re-Os isotope system permits the direct absolute dating of the metal phase in iron meteorites. Indirect dating of iron meteorites has been achieved in the past through the Rb-Sr, K-Ar, and most recently, Sm-Nd for silicate inclusions, where present. Relative dating has been obtained directly by extensive studies of the short-lived system Pd-107/Ag-107 for the metal and sulfide phases and indirectly using I-129/Xe-129 in silicate and sulfide inclusions. SEPARATION OF SPALLATION AND TERRESTRIAL C-14 IN CHONDRITES Abstract Only c90

R. G. Cresswell, R. P. Beukens, and J. C. Rucklidge *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 341-342 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Weathering products and contamination severely hamper our ability to accurately measure the C-14 spallation component in meteorites, but can give insights into a sample's terrestrial history. A procedure was developed to measure the C-14 in these components using CO and CO2 separations from temperature extractions from 200-500 mg of material. The Bruderheim (L6) chondrite was chosen as a standard following the practice of previous researchers, crosschecked against Peace River (L6), Abee (EH4), and Juvinas (EUC). Low temperature fractions (less than 900 C) give C-14 signatures consistent with a modern terrestrial C-14 source; melt fractions show elevated levels attesting to a spallogenic origin. Higher yields of CO in the melt fraction are less affected by the low levels of experimental contamination than the CO2. This fraction gave a mean CO:CO2 ratio in Bruderheim of 81.6 +/- 7.7; the ratio of the spallation component is 79.8 +/- 8.1. These values suggest equilibrium release of gases on the olivine-silica-pyroxene-iron buffer. This is corroborated by approximately equal release of the two components at 900 C. The chondrites gave an average saturation level of 54.3 +/- 2.9 dpm/kg; the achondrite gave 49.6 +/- 2.0 dpm/kg. No clear correlation with oxygen content is apparent, though shielding effects have yet to be evaluated. A further evaluation of this subject matter is given. Author (revised)

NEAR-INFRARED SPECTRA OF THE MARTIAN SURFACE: READING BETWEEN THE LINES Abstract Only

D. Crisp and J. F. Bell, III (National Aeronautics and Space Administration. Ames Research Center, Moffett Field, CA.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 343-344 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Moderate-resolution near-infrared (NIR) spectra of Mars have been widely used in studies of the Martian surface because many candidate surface materials have distinctive absorption features at these wavelengths. Recent advances in NIR detector technology and instrumentation have also encouraged studies in this spectral region. The use of moderate spectral resolution has often been justified for NIR surface observations because the spectral features produced by most surface materials are relatively broad, and easily discriminated at this resolution. In spite of this, NIR spectra of Mars are usually very difficult to interpret quantitatively. One problem is that NIR surface absorption features are often only a few percent deep, requiring observations with great signal-to-noise ratios. A more significant problem is that gases in the Martian atmosphere contribute numerous absorption features at these wavelengths. Ground-based observers must also contend with variable absorption by several gases in the Earth's atmosphere (H2O, CO2, O3, N2O, CH4, O2). The strong CO2 bands near 1.4, 1.6, 2.0, 2.7, 4.3, and 4.8 micrometers largely preclude the analysis of surface spectral features at these wavelengths. Martian atmospheric water vapor also contributes significant absorption near 1.33, 1.88, and 2.7 micrometers, but water vapor in the Earth's atmosphere poses a much larger problem to ground-based studies of these spectral regions. The third most important NIR absorber in the Martian atmosphere is CO. This gas absorbs most strongly in the relatively-transparent spectral windows near 4.6 and 2.3 micrometers. It also produces 1-10 percent absorption in the solar spectrum at these NIR wavelengths. This solar CO absorption cannot be adequately removed by dividing the Martian spectrum by that of a star, as is commonly done to calibrate ground-based spectroscopic observations, because most stars do not have identical amounts of CO absorption in their spectra. Here, we describe tow effective methods for eliminating contamination of Martian surface spectra by absorption in the solar, terrestrial, and Martian atmospheres. Both methods involve the use of very-high-resolution spectra that completely resolve the narrow atmospheric absorption lines. Author (revised)

POROSITY AND THE ECOLOGY OF ICY SATELLITES Abstract Only **c90**
Steven K. Croft *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 347-348 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The case for a significant role for porosity in the structure and evolution of icy bodies in the Solar System has been difficult to establish. We present a relevant new data set and a series of structure models including a mechanical compression, not thermal creep, model for porosity that accounts satisfactorily for observed densities, moments of inertia, geologic activity, and sizes of tectonic features on icy satellites. Several types of observational data sets have been used to infer significant porosity, but until recently, alternative explanations have been preferred. Our first area of concern is the occurrence of cryovolcanism as a function of satellite radius; simple radiogenic heating models of icy satellites suggest minimum radii for melting and surface cryovolcanism to be 400 to 500 km, yet inferred melt deposits are seen on satellites half that size. One possible explanation is a deep, low conductivity regolith which lowers conductivity and raises internal temperatures, but other possibilities include tidal heating or crustal compositions of low conductivity. Our second area of concern is the occurrence and magnitude of tectonic strain; tectonic structures have been seen on icy satellites as small as Mimas and Proteus. The structures are almost exclusively extensional, with only a few possible compression Al features, and inferred global strains are on the order of 1 percent expansion. Expansions of this order in small bodies like Mimas and prevention of late compressional tectonics due to formation of ice mantles in larger bodies like Rhea are attained only in structure models including low-conductivity, and thus possibly high porosity, crusts. Thirdly, inferred moments of inertia less than 0.4 in Mimas and Tethys can be explained by high-porosity crusts, but also by differentiation of a high density core. Finally, the relatively low densities of smaller satellites like Mimas and Miranda relative to larger neighbors can be explained by deep porosity, but also by bulk compositional differences. Recent work has strengthened the case for significant porosity. Halley's nucleus was found to have a density near 0.6 g/cu cm, Janus and Epimethus were proposed to have densities near 0.7 g/cu cm, densities almost certainly due to high porosity. The irregular-spherical shape transition of icy satellites was quantitatively explained by low conductivity regoliths. A creative structure/thermal history model for Mimas simultaneously accounts quantitatively for Mimas' low density and moment of inertia by invoking initial high-porosity and subsequent compaction in the deep interior by thermal creep. The main problem with this promising model is that approximately 7 percent predicts a reduction in Mimas' radius, implying significant compressional failure and prevention of extensional tectonics, in contradiction to the observed extensional features and inferred 1 percent expansion in radius. TECTONICS ON TRITON Abstract Only
Steven K. Croft *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 349-350 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Tectonic features on Triton have been mapped as part of a larger study of the geology of Triton. Few purely tectonic structures are found on Triton: some grabens and possibly some compressive ridges. However, most of the other structures seen (primarily cryovolcanic in origin) exhibit tectonic control. A regional tectonic network has the following dominant orientations: N-S, E-W, NE-SW, and NW-SE. Most of the orientations are consistent with tidal deformations related to Triton's decreasing orbital radius. Localized quasi-concentric patterns may be due to interior processes such as mantle plumes. Author (revised)

POST-IMPACT ALTERATION OF THE MANSON IMPACT STRUCTURE Abstract Only **c46**
L. J. Crossey and P. McCarville *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 351-352 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Core materials from the Manson impact site (Manson, Iowa) are examined in order to evaluate post-impact alteration processes. Diagenetic interpretation of post-impact events is based on petrologic, mineralogic, and geochemical investigation of core materials including the following: target strata, disturbed and disrupted strata, ejecta, breccias, microbreccias, and impact melt. The diagenetic study utilizes research cores obtained by the continental scientific drilling project (CSDP) at the Manson structure, as well as core and cuttings of related materials. Samples include impactites (breccias, microbreccias, and melt material), crater fill material (sedimentary clast breccias), disturbed and disrupted target rocks, and reference target material (Amoco Eisheid No. 1 materials). The study of multiple cores will permit development of a regional picture of post-impact thermal history. The specific objectives are as follows: (1) provide a detailed description of authigenic and alteration mineralogy from diverse lithologies encountered in research drill cores at the Manson impact structure, and (2) identify and relate significant post-impact mineral alteration to post-impact thermal regime (extent and duration). Results will provide mineralogical and geochemical constraints on models for post-impact processes including the following: infilling of the crater depression; cooling and hydrothermal alteration of melt rocks; and subsequent long-term, low-temperature alteration of target rocks, breccias, and melt rocks. Preliminary petrologic and x-ray diffraction examination of fracture linings and void fillings from research core M1 indicate the presence of quartz, chlorite, mixed-layer clays, gypsum/anhydrite, calcite, and minor pyrite. MODEL OF OPTICAL SCATTER FROM MICROIMPACTS ON THE HUBBLE TELESCOPE Abstract Only **c74**
L. B. Crowell *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 353-354 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The investigation and modelling of optical scatter from damaged or contaminated mirrors is of interest to those who wish to estimate the working life cycle of an optical system. A space born telescope faces a threat to its survival from naturally occurring micrometeoroids and man-made debris. High velocity, in the range of 4 to 14 km/s, impacts of small particles, in the range of 1 to 100 microns, will produce small craters on the impacted surface. These microcraters will typically have a size range of 3 to 300 microns for debris impacts and 6 to 600 microns for micrometeoroid impacts. If the microcraters accumulate on a telescope mirror, there will be an increase in optical scatter and a loss of image resolution. The micrometeoroid model of Cour-Palais and the orbital debris model of Kessler have been encoded in a computer program (SPENV) by the author. The output from this program has been matched with previous calculations and compared with impact data on the LDEF satellite. Subsequent work has been done to marry this computer program with an algorithm to compute optical scatter. The optical scatter algorithm employs Mie theory of scatter from small particles. VOLCANISM IN SOUTHERN GUINEVERE PLANITIA, VENUS: REGIONAL VOLCANIC HISTORY AND MORPHOLOGY OF VOLCANIC DOMES Abstract Only
David A. Crown, Ellen R. Stofan, and Jeffrey J. Plaut *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 355-356 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Guinevere Planitia is a low-lying region located between the highlands of Beta Regio and Eistla Regio. Analyses of Pioneer Venus, Goldstone, and Arecibo radar data suggested that the surface of Guinevere Planitia is dominated by volcanism, primarily in the form of bright, dark, and mottled plains units. Also identified in this region was the Beta-Eistla Deformation Zone, composed of ovoids and discontinuous segments of lineament belts that have been embayed by the surrounding plains. The resolution of Magellan SAR images allows detailed investigations of the volcanic deposits found in the area in order to determine the types of eruptive activity which have occurred and to constrain the regional volcanic history. Analyses of an area of southern Guinevere Planitia between 0-25 deg N and 300-330 deg indicate the presence of a wide variety of volcanic land forms, including large shield volcanoes, widespread plains, lava flow fields, and small domes, cones, and shields as well as coronae and other circular structures that have associated volcanic deposits. ANOMALOUS REE PATTERNS IN UNEQUILIBRATED ENSTATITE CHONDRITES: EVIDENCE AND IMPLICATIONS Abstract Only c90
Ghislaine Crozaz and Weibiao Hsu *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 357-358 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

We present here a study of Rare Earth Element (REE) microdistributions in unequilibrated enstatite chondrites (EOC's). Although the whole rock REE contents are similar in both unequilibrated and equilibrated chondrites, the host minerals of these refractory elements are different. In the least equilibrated ordinary chondrites (UOC's), the REE reside mainly in glass whereas, in their more equilibrated counterparts, the bulk of the REE is in calcium phosphate, a metamorphic mineral that formed by oxidation of phosphorous originally contained in metal. In the smaller group of enstatite (E) chondrites, calcium phosphate is absent and the phase that contains the highest REE concentrations is a minor mineral, CaS (oldhamite), which contains approximately 50 percent of the total Ca present. In E chondrites, elements typically considered to be lithophiles (such as Ca and Mn) occur in sulfides rather than silicates. This indicates formation under extremely reducing conditions, thus in a region of the solar nebula distinct from those that supplied the more abundant ordinary and carbonaceous chondrites. Previously, we observed a variety of REE patterns in the oldhamite of UEC's; they range from almost flat to some with pronounced positive Eu and Yb anomalies. Here, we searched for complementary REE patterns in other minerals from E chondrites and found them in the major mineral, enstatite. Whenever Eu and Yb anomalies are present in this mineral, they are always negative. Author (revised)

COMPARISON OF THE DISTRIBUTION OF LARGE MAGMATIC CENTERS ON EARTH, VENUS, AND MARS Abstract Only
L. S. Crumpler *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 359-360 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Volcanism is widely distributed over the surfaces of the major terrestrial planets: Venus, Earth, and Mars. Anomalous centers of magmatic activity occur on each planet and are characterized by evidence for unusual concentrations of volcanic centers, long-lived activity, unusual rates of effusion, extreme size of volcanic complexes, compositionally unusual magmatism, and evidence for complex geological development. The purpose of this study is to compare the characteristics and distribution of these magmatic anomalies on Earth, Venus, and Mars in order to assess these characteristics as they may relate to global characteristics and evolution of the terrestrial planets. A catalog summarizing the location and characteristics of 1663 volcanic and magmatic centers identified in Magellan radar images of the surface of Venus is in final preparation to be submitted as a Geological Society of America Special Paper. The following is a brief summary preview of the contents and methods used in assembling the final data set, the organization of the catalog, and other notes of interest to potential users. SYNTHESIS OF GLOBAL THEMATIC MAPPING, VENUS: GEOLOGIC CORRELATIONS/QUESTIONS FOR THE MAGELLAN GRAVITY MISSION Abstract Only
L. S. Crumpler, J. C. Aubele, and J. W. Head *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 363-364 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

An important characteristic of the Magellan mission and the resulting data is that it is both global in coverage as well as extremely high in resolution. As a result, global questions may be addressed based on the constraints of extremely detailed geological evidence. An important first step in the task of interpreting the global geological record will be a synthesis of the primary geological characteristics and their relationship to significant questions. The following is a brief synthesis based on a comparison of mapped distributions, initial interpretations, and some questions that these results raise. Author (revised)

LARGE VOLCANOES ON VENUS: EXAMPLES OF GEOLOGIC AND STRUCTURAL CHARACTERISTICS FROM DIFFERENT CLASSES Abstract Only
L. S. Crumpler, J. W. Head, and J. C. Aubele *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 365-366 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Large volcanoes characterized by radial lava flows and similar evidence for a topographic edifice are widely distributed over the surface of Venus and geologically diverse. Based on the global identification of more than 165 examples and preliminary geologic mapping, large volcanoes range from those characterized geologically as simple lava edifices to those bearing evidence of complexly developed volcanic and structural histories. Many large volcanoes exhibit characteristics transitional to other large magnetic center types such as coronae and novae. In this study, we examine the geology and structure of several type examples of large volcanoes not addressed in previous studies which are representative of several of the morphological classes. REGIONAL MANTLE UPWELLING ON VENUS: THE BETA-ATLA-THEMIS ANOMALY AND CORRELATION WITH GLOBAL TECTONIC PATTERNS Abstract Only
L. S. Crumpler, J. W. Head, and Jayne C. Aubele *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 367-368 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The morphology and global distribution of volcanic centers and their association with other geological characteristics offers significant insight into the global patterns of geology, tectonic style, thermal state, and interior dynamics of Venus. Magellan data permit the detailed geological interpretation necessary to address questions about interior dynamics of Venus particularly as they reflect relatively physical, chemical, and thermal conditions of the interior. This paper focuses on the distribution of anomalous concentrations of volcanic centers on Venus and regional patterns of tectonic deformation as it may relate to the identification of global internal anomalies, including mantle dynamic, petrological, or thermal patterns.

THE GRANULITE SUITE: IMPACT MELTS AND METAMORPHIC BRECCIAS OF THE EARLY LUNAR CRUST Abstract Only **c46**

J. A. Cushing, G. J. Taylor, M. D. Norman, and K. Keil *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 369-370 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

The granulite suite consists of two major types of rocks. One is coarse-grained and poikilitic with many euhedral crystals of olivine and plagioclase. These characteristics indicate crystallization from a melt; the poikilitic granulites are impact melt breccias. The other group is finer-grained and granoblastic, with numerous triple junctions; the granoblastic granulites are metamorphic rocks. Compositional groups identified by Lindstrom and Lindstrom contain both textural types. Two pyroxene thermometry indicates that both groups equilibrated at 1000 to 1150 C. Calculations suggest that the granoblastic group, which has an average grain size of about 80 microns, was annealed for less than 6 x 10 exp 4 y at 1000 C, and for less than 2500 y at 1150 C. Similar equilibration temperatures suggest that both groups were physically associated after impact events produced the poikilitic melts. Granulitic impactites hold important information about the pre-Nectarian bombardment history of the Moon, and the composition and thermal evolution of the early lunar crust. Granulitic impactites are widely considered to be an important rock type in the lunar crust, but how they formed is poorly understood. Metal compositions and elevated concentrations of meteoritic siderophile elements suggest that most lunar granulites are impact breccias. Their occurrence as clasts in approximately 3.9 Ga breccias, and Ar-(40-39) ages greater than or = 4.2 Ga for some granulites show that they represent a component of the lunar crust which formed prior to the Nectarian cataclysm. Petrographic characteristics of lunar granulites indicate at least two endmember textural variants which apparently formed in fundamentally different ways. One type has granoblastic textures consisting of equant, polygonal to rounded grains, and abundant triple junctions with small dispersions around 120 degrees indicating a close approach to textural equilibrium. As suggested by many authors, granoblastic granulites probably formed by subsolidus annealing and recrystallization of fragmental or glassy protoliths. Examples of this type include 15418, 78155, and 79215. The other textural type consists of poikilitic to poikiloblastic rocks with euhedral to subhedral plagioclase and olivine enclosed by interstitial pyroxene. In some cases, the texture resembles that of an orthocumulate. Examples of this type include 60035, 67955, and 77017. Rounding of grain edges is common in poikilitic granulites, but the regular crystal shapes and widely dispersed dihedral angles show they are far from textural equilibrium. The textures of poikilitic granulites are more consistent with the formation of these rocks by crystallization from a melt than by subsolidus metamorphism. A few samples have been recognized with textural characteristics transitional between those of the granoblastic and poikiloblastic endmembers (e.g., 72559, 78527). Pyroxene compositions taken from the literature and determined for this study by electron microprobe were used to calculate equilibration temperatures. The Kretz Ca transfer (solvus) thermometer and the Lindsley and Anderson graphical method both give similar temperatures, which range from approximately 1000 to 1150 C. There is no apparent temperature difference between granoblastic and poikilitic varieties, but there is a hint in these data that the more ferroan varieties equilibrated to lower temperatures. Additional studies are in progress to test this possibility.

GALILEO EM-2 CONTRIBUTIONS TO THE LUNAR CONTROL NETWORK Abstract Only

M. E. Davies, T. R. Colvin (RAND Corp., Santa Monica, CA.), M. J. S. Belton (Kitt Peak National Observatory, Tucson, AZ.), and R. Greeley *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 371 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

A local control network is being developed using Galileo images that cover the region north of the Apollo area and lie between 10 and 100 degrees east longitude. This network is tied to the Apollo control network and will have a positional accuracy of approximately 500-1500 m. This region has been photographed by Earth-based telescopes and the Mariner 10 and Lunar Orbiter spacecraft, but the Gallileo images are preferred for control because of their superior viewing angles, resolution, and Galileo's geometrically stable sensor. Based on Davies et al., 1987, the potential accuracy of the near-side Apollo network is estimated to be between 50 and 300 m. The laser ranging retroreflector locations at the Apollo 11, 14, and 15 sites and the Lunikhod 2 site have been determined with an accuracy of about 10 m. The locations of the ALSEP transmitters relative to the retroreflectors have also been measured. These known coordinates are used to estimate errors in the Apollo network. The telescopic control is approximately bounded by 75 degrees north and south latitude and 75 degrees east and west longitudes. The accuracy of the telescopic network is thought to be about one to two km. Thus, the Galileo network might improve coordinates in the telescopic area as well as north and east of it.

IRON AND NICKEL ISOTOPIC MASS FRACTIONATION IN DEEP-SEA SPHERULES Abstract Only **c46**

Andrew M. Davis and Donald E. Brownlee (Washington Univ., Seattle.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 373-374 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Magnetite-wuestite spherules collected from deep-sea sediments are thought to have originally been Fe-Ni metal particles at the top of the atmosphere that were oxidized and melted during entry into the earth's atmosphere. Some likely sources for the metal particles are Fe-Ni interplanetary dust particles (IDP's) and metal or sulfide from stony IDP's that separated after melting. Davis et al. reported that four of these spherules are enriched in the heavy isotopes of iron, with enrichments of 8-23%/amu. We have developed a technique for analysis of both iron and nickel isotopes on the same ion microprobe spot and have applied this technique to a number of deep-sea spherules in order to better understand the processes leading to isotopic mass fractionation. Eight spherules show iron and nickel isotopic mass fractionation, with iron and nickel enriched in the heavy isotopes by 10-19%/amu and 4-32%/amu, respectively. If the mass fractionations are due to Rayleigh fractionation during evaporation, these spherules lost 76-94% of their original mass. We have analyzed the four magnetite-wuestite spherules for which iron isotopic data were reported by Davis et al. as well as four new spherules.

TRACE ELEMENT DISTRIBUTIONS IN PRIMITIVE ACHONDRITES Abstract Only **c90**

Andrew M. Davis, Martin Prinz (American Museum of Natural History, New York, NY.), and Michael K. Weisberg (American Museum of Natural History, New York, NY.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 375-376 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

The primitive achondrites have approximately chondritic bulk chemical composition but achondritic textures. Clayton et al. show that nine of these meteorites, the acapulcoites and the lodranites, have similar oxygen isotopic compositions. The acapulcoites appear to be highly metamorphosed, but undifferentiated meteorites of chondritic composition; whereas, the lodranites appear to have lost a feldspathic partial melt. In order to learn more about metamorphic processes and partial melt removal, we have measured the trace element compositions of constituent phases of a number of primitive achondrites by ion microprobe. We have analyzed two acapulcoites, Acapulco and ALH81261 (paired with ALH77081), and three londranites, Lodran, LEW88280, and MAC88177. In addition, we analyzed LEW88663, which has the bulk composition, mineral chemistry, and oxygen isotopic composition of L-chondrites, but is metal-free and has an achondrite texture; and Divnoe, a plagioclase-poor, olivine-rich primitive achondrite with an oxygen isotopic composition similar to that of the group IAB iron meteorites. These meteorites show a variety of REE patterns in their constituent phases, and there are consistent differences between acapulcoites and lodranites that are consistent with removal of a LREE- and Eu-enriched melt that is apparently responsible for the low plagioclase content of lodranites. Dohnanyi established that the size distribution of a collisionally relaxed population is a power-law with a -3.5 slope (incremental diameter), provided that: (1) collisional parameters are independent of size and (2) there is no lower limit on the population size for shattering impacts. In the course of studying collisional effects over a wide range of asteroid sizes (cm up to hundreds of km range), we have investigated the consequences of relaxing the second condition, while maintaining the first one. SMALL VOLCANOES IN TEMPE TERRA, MARS: THEIR DETAILED MORPHOMETRY AND INFERRED GEOLOGIC SIGNIFICANCE Abstract Only

P. A. Davis and K. L. Tanaka *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 379-380 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

The Tempe Terra province contains a variety of volcanic landforms that range in size from small vents (less than 10 km in diameter) to moderately sized volcanoes (150 km in diameter). The volcanoes are aligned along the dominant northerly and northeasterly trends of the faults in this region, and many of the volcanoes occur on grabens. Some workers have speculated on the nature of some of the volcanoes on the basis of their general morphology, shadow measurement height, lateral dimension, and geologic setting. As part of a larger study, we have obtained detailed photoclinometric profiles across five of the more conspicuous small volcanoes in the Tempe Terra region. For these data, we extracted for each volcano its flank width and edifice height and the width and depth of its summit crater. We statistically compared these dimensions for each volcano with a set of average dimensions for each type of terrestrial volcanic feature listed in Pike and Clow (1981). These comparisons indicate that the morphometries of the Martian volcanoes 1, 2, and 3 most closely match Earth's cratered basaltic lava shields, and the morphometries of volcanoes 4 and 5 are similar to those of terrestrial basaltic tuff rings. Derived from text

SHALLOW CRUSTAL DISCONTINUITIES AND GRABEN AND SCARP FORMATION IN THE THARSIS REGION OF MARS Abstract Only

P. A. Davis, K. L. Tanaka, and M. P. Golombek (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 381-382 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

We recently obtained photoclinometric profiles across all simple grabens and erosional landforms (e.g., troughs, pits, wall-valley heads, and scarps that are bounded above and below by flat surfaces) that occur within Tempe Terra. These data, together with similar data that we obtained for Syria, Sinai, and Lunae Plana and the Alba Patera region, allow regional examination of shallow crust Al discontinuities between latitude 30 deg. S and 50 deg. N and longitude 50 deg. W and 112 deg. W. The profile for each simple graben was used with an appropriate structural model to estimate the depth to the base of the faulted layer. The depths of erosional wall scarps may also indicate the depths of mechanical discontinuities such as a local lithologic or cryospheric boundary. Examination of these data indicates a surprisingly consistent set of shallow crust Al discontinuities for the Tharsis region at depths of 0.4-0.6 km, 1.0-1.4 km, and 2 km; the maximum depth of the features in most study areas appears to be about 4 km. The concentration of values between 0.4 and 0.6 km in most scarp and some faulted-layer depth data is similar to the range in estimated thicknesses of individual exposed Noachian and Hesperian plains units in the Tharsis region. The regional depth data also show two modes near 1 and 2 km in some study areas and a maximum depth near 4 km in most study areas; the faulted-layer depths in excess of 4 km at Alba Patera occur near the summit of the caldera and could be attributed to volcanic loading. Our detailed examination of these depth data includes the following observations: (1) The mode at 1.0-1.4 km depth transcends age and geologic setting in this broad study area; (2) The 2-km mode is most obvious at Alba Patera and moderately well developed at Syria and Sinai Plana, but it is muted at Tempe Terra, which is in the same latitude range as Alba Patera but older; and (3) The 2-km-depth mode is not present in all areas that have features of Amazonian age. We suggest two possible explanations for our observations in the Tharsis region. Derived from text

CHARACTERISTICS OF ARACHNOIDS FROM MAGELLAN DATA Abstract Only

C. B. Dawson and L. S. Crumpler *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 383-384 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Current high resolution Magellan data enables more detailed geological study of arachnoids, first identified by Barsukov et al. as features characterized by a combination of radar-bright, concentric rings and radiating lineations, named 'arachnoids' on the basis of their spider and web-like appearance. Identification of arachnoids in Magellan data has been based on SAR images, in keeping with the original definition. However, there is some overlap by other workers in identification of arachnoids, corona (predominantly bright rings), and novae (predominantly radiating lineations), as all of these features share some common characteristics. Features used in this survey were chosen based on their classification as arachnoids in Head et al.'s catalog and on SAR characteristics matching Barsukov et al.'s original definition. The 259 arachnoids have been currently identified on Venus, all of which were considered in this study. Fifteen arachnoids from different regions, chosen for their 'type' characteristics and lack of deformation by other regional processes, were studied in depth, using SAR and altimetric data to map and profile these arachnoids in an attempt to better determine their geologic and altimetric characteristics and possible formation sequences. A METHOD TO DETERMINE ASTEROID POLES Abstract Only c90

G. DeAngelis *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 385-386 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

The determination of spin axis and shape is well known to be of fundamental importance for studies about the rotational and physical properties of asteroids. In particular, knowledge that the pole coordinate distribution is random or not could indicate the probable non-Maxwellian distribution of asteroid spin axes, while the distribution in terms of size and shape could place important constraints on the theories about the collisional history of some individual asteroids, of asteroid families, and of the asteroid population as a whole. Many kinds of methods have been developed to determine pole coordinates. An EA method is presented, from which it is possible to obtain the solution with no trial poles, but with a simultaneous least square fit on both the E and A part. Results for rotational and shape parameters were obtained for 18 asteroids: the values of the obtained parameters are generally in close agreement with those of others. Derived from text

CATHODOLUMINESCENCE PROPERTIES OF COMPONENTS IN ENSTATITE CHONDRITES Abstract Only c90

John M. DeHart and Gary E. Lofgren (National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, TX.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 387-388 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

As a group, the enstatite chondrites are notable by the extremely low FeO content of most of their silicates. This property predisposes many of these materials to emit Cathodoluminescence (CL). Since examination of the CL properties of meteoritic components in ordinary and carbonaceous chondrites have proven to be a useful technique, we have initiated a survey of the enstatite chondrites in order to better characterize the chemical and physical properties of their luminescing phases. Because of the diversity encountered in this study, it is first necessary to describe the number and types of materials observed to emit CL in these meteorites. Two CL techniques were used. First, the initial survey work was conducted at low magnification using a Nuclide (now MAAS) Luminoscope mounted to a Wild MP binocular microscope equipped for photomicroscopy. The beam conditions used were 14 +/- KeV and 7 +/- 1 milliamps, with the beam focussed to the diameter of the field of view of the microscope at 20x (appox. 1.25 cm). Photomosaics were produced for each section using Ecktar 1000 film and an exposure time of 15 to 30 seconds. Second, high magnification (400x) photos were obtained of individual components of interest by mounting a 35mm camera to the optical system of the Cameca Camebax microprobe located at the Johnson Space Center. Beam conditions used were 15 KeV and 600 nA. Ecktar 1000 film was also used, but exposure times of 6 minutes were necessary to produce a useful image. The components in E chondrites that produce CL can be divided into four broad categories. These are clasts and aggregates, chondrules, matrix components, and refractory objects. Components in each category are discussed. Derived from text

CLASSIFICATION OF MARTIAN DELTAS Abstract Only

R. A. DeHon *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 389-390 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Water-borne sediments in streams are deposited, upon eventual cessation of flow, either as deltas or as alluvial fans or plains. Deltas and alluvial fans share a common characteristic; both may be described as deposition Al plains at the mouth of a river or stream. A delta is formed where a stream or river deposits its sedimentary load into a standing body of water such as an ocean or lake. An alluvial fan is produced where a stream loses capacity by a greatly decreased gradient. A delta has subaerial and subaqueous components, but an alluvial fan is entirely subaerial. In terrestrial conditions, deltas and alluvial fans are reasonably distinct landforms. The juxtaposition of concomitant features composition and internal structure are sufficiently explicit as to avoid any confusion regarding their proper identification on Mars, the recognition of deltas and their distinction from alluvial fans is made difficult by low resolution imaging. Further, although it may be demonstrated that standing bodies of water existed on the surface of Mars, many of these bodies may have existed for extremely short periods of time (a few days to months); hence, distinctive shoreline features were not developed. Thus, in an attempt to derive a Martian classification of deltas, the inclusion of wholly subaerial deposits may be unavoidable. A simple, broad, morphological classification of Martian deltas, primarily on planimetric shape, includes digitate deltas, fan-shaped deltas, and re-entrant deltas. A fourth, somewhat problematical class includes featureless plains at the end of many valley systems. Derived from text

THE Fe/Mn CONSTRAINT ON PRECURSORS OF BASALTIC ACHONDRITES Abstract Only **c90**

Jeremy S. Delaney and Joseph S. Boesenberg *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 391-392 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Most achondritic meteorites have Fe/Mn ratios that are lower than those of carbonaceous chondrites and of course are lower than the solar system abundance ratio of these elements. Models of the origin of achondritic assemblages must, therefore, account for these ratios. Fe/Mn ratios are suggested to be distinctive for samples from each achondrite parent body and for the Earth and Moon, but the correspondence between the Fe/Mn systematics of achondrites and chondritic precursors is unclear. Most models of achondrite genesis involve magmatic differentiation of chondritic precursors. The Fe/Mn difference between achondrites and chondrites is particularly significant since Fe and Mn are geochemically similar elements with similar partitioning behavior in familiar magmatic systems and are generally coupled during crystal-liquid fractionation. In contrast, however, Mn is more volatile than Fe in a nebular setting. Variation of Fe/Mn ratios based on the relative volatility of these elements in the early nebula provides a constraint for models by which the basaltic achondrites (with Fe/Mn ratios approximately = 25-50) are derived from mixtures of nebular components that were enriched in volatile components such as Mn. However, such volatile enriched components have not been identified in chondrites. When the abundance in achondrites of elements of similar volatility is examined, anomalies appear. For example, Na is massively depleted in basaltic achondrites when compared to Mn. These anomalies might be explained using current models but the alternative hypothesis, that Fe/Mn ratio is controlled not by nebular volatility constraints, but by planetary differentiation should be explored. COMPOSITIONAL HETEROGENEITY WITHIN A DUMBBELL-SHAPED APOLLO 15 GREEN GLASS: EVIDENCE FOR SIMULTANEOUS ERUPTION OF DIFFERENT MAGMAS Abstract Only

J. W. Delano *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 393-394 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The Apollo 15 green glasses that occur most prominently in 15425, 15426, and 15427 consist of compositionally distinct groups. The six groups that have thus far been defined are thought to represent different batches of magma that were erupted as fire-fountains, probably at different times in lunar history; although isotopic analyses of representative glasses within some of these groups have not yet found any differences in age at the +/- 100 Ma precision. While the petrogenesis of these picritic magmas has been contentious, the discovery of a compositionally heterogeneous, dumbbell-shaped green glass raises additional questions and problems about their origin. OXIDATION STATE OF THE EARTH'S UPPER MANTLE DURING THE LAST 3800 MILLION YEARS: IMPLICATIONS FOR THE ORIGIN OF LIFE Abstract Only **c46**

J. W. Delano *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 395-396 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

A popular, as well as scientifically rigorous, scenario for the origin of life on Earth involves the production of organic molecules by interaction of lightning (or other forms of energy) with a chemically reducing atmosphere in the early history of Earth. Experiments since the 1950's have convincingly demonstrated that the yield of organic molecules is high when the atmosphere contains molecular hydrogen, methane, ammonia, and water vapor. Additional work has also shown that such a highly reducing atmosphere might not, however, have been sufficiently long-lived in the presence of intense solar ultraviolet radiation for life to have formed from it. One way of maintaining such an atmosphere would be to have a continual replenishment of the reduced gases by prolonged volcanic outgassing from a reducing of Earth's interior. The length of time that this replenishment might need to continue is in part constrained by the flux of asteroids onto the Earth's surface containing sufficient energy to destroy most, if not all, life that had developed up to that point in time. If a reducing atmosphere is a key ingredient for the origin of life on Earth, the time of the last environmental sterilization due to large impacts would be an important constraint. In a deep marine setting (e.g., hydrothermal vent), the last global sterilization might have occurred at 4200-4000 Ma. On the Earth's surface, the last global sterilization event might have occurred at

4000-3700 Ma. If these are meaningful constraints, how likely is it that a reducing atmosphere could have survived on the Earth until about 3800 Ma ago? Due to the importance of replenishing this atmosphere with reducing components by volcanic outgassing from the mantle, geochemical information on the history of the mantle's oxidation state would be useful for addressing this question. Geochemical and experimental data discussed in this abstract suggest that extrusive mafic volcanics derived from the upper mantle have had oxidation states near the fayalite-magnetite quartz buffer throughout the last 3800 Ma. At magmatic temperatures, the gases released from volcanoes having this oxidation state would have been, as they are today, composed dominantly of carbon dioxide and water vapor, and would not contain the ingredients for maintaining a reducing atmosphere. Consequently, geochemical data do not favor the survival of a reducing atmosphere until about 3800 Ma. Alternative venues and pathways for the origin of life need to be investigated (e.g., hydrothermal vents along oceanic ridges). Derived from text

SORET DIFFUSION: A POSSIBLE CAUSE OF COMPOSITIONAL HETEROGENEITY WITHIN TEKTITES Abstract Only c90

J. W. Delano, Y.-G. Liu (Oregon State Univ., Corvallis.), and R. A. Schmitt (Oregon State Univ., Corvallis.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 397-398 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Although a terrestrial origin for tektites is well-established on geochemical evidence, the physical processes involved in tektite formation have been largely ignored by geochemists and petrologists. For example, two observations that potentially bear on the physics of their origin are the following: (1) The flange of an australite is often more heterogeneous than its core; and (2) microtektites are compositionally more diverse than tektites. The first observation contradicts the traditional view of flange formation since a second heating to super-liquidus temperatures during atmospheric re-entry should, by chemical diffusion and mixing, have tended to homogenize the melt as it flowed off the leading edge of the core to form the flange. Analyses of an australite flange have been performed by electron microprobe. The results of those analyses emphasize the magnitude of the heterogeneity, as well as the well-defined elemental correlations that may constrain the process responsible for it. The second observation that the bulk compositions of microtektites are more divers than the tektites within the same strewnfield is a well-known characteristic, for which no quantitative explanation has been offered. The current investigation has involved the analysis of 43 Australasian microtektites from the Wharton Basin by electron microprobe, as well as trace-element abundances on fifteen of these microtecktites by INAA. ISOTOPIC AND TRACE ELEMENT CHARACTERISTICS OF AN UNUSUAL REFRACTORY INCLUSION FROM ESSEBI Abstract Only c92

E. Deloule, A. K. Kennedy, I. D. Hutcheon, and A. ElGoresy (Max-Planck-Inst. fuer Kernphysik, Heidelberg, Germany.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 399-400 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

The isotopic and chemical properties of Ca-Al-rich inclusions (CAI) provide important clues to the early solar nebula environment. While the abundances of refractory major and trace elements are similar to those expected for high temperature condensates, the variety of textural, chemical, and isotopic signatures indicate most CAI experienced complex, multi-stage histories involving repeated episodes of condensation, evaporation, and metamorphism. Evidence of multiple processes is especially apparent in an unusual refractory inclusion from Essebi (URIE) described by El Goresy et al. The melilite (mel)-rich core of URIE contains polygonal framboids of spinel (sp) and hibonite (hb) or sp and fassaite (fas) and is surrounded by a rim sequence consisting of five layers. In contrast to rims on Allende, the mineralogy of the URIE rim layers becomes increasingly refractory from the core outwards, ending in a layer of spinel-Al2O3 solid solution + Sc-rich fassaite. The chemical and mineralogical features of URIE are inconsistent with crystallization from a homogeneous melt, and El Goresy et al. proposed a multi-step history involving condensation of sp + hb and aggregation into framboids, capture of framboids by a refractory silicate melt droplet, condensation of rim layers, and alteration of mel to calcite and feldspathoid. The PANURGE ion probe was used to investigate the isotopic and trace element characteristics of URIE to develop a more complete picture of the multiple processes leading to formation and metamorphism. THE CORRELATION OF ALKALIS AND ALUMINUM DURING HIGH-TEMPERATURE VOLATILIZATION OF ALBITE AND NEPHELINE Abstract Only c25

Yu. P. Dikov, M. V. Gerasimov, O. I. Yakovlev, and F. Wlotzka (Max-Planck-Inst. fuer Chemie, Mainz, Germany.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 403-404 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Our previous study of high-temperature evaporation of mafic targets has shown a systematic enrichment of newly-formed condensates in silicon and alkalis and depletion in refractory elements (Al, Ca, Ti). This effect, which is consistent with the volatility of the elements, was also tested for several experiments with acidic targets. In one case it was the impact evaporation of granite targets using a light-gas gun facility. Analyses of the condensate which was collected during the impact show that it was enriched in Al and Na so that the composition of the condensate became close to nepheline. In the work of Nagahara, an incongruent evaporation of alkali feldspars under stationary conditions has been also proposed. These discoveries required a more detailed study of high-temperaure evaporation of monomineralic Al-silicate targets. In these experiments, we have used samples of oligoclase and of nepheline. Vaporization of samples was performed in a hermetic cell filled with helium at normal temperature and pressure using a powerful Nd-laser focused on the sample. Laser pulses had the following parameters: luminous energy approximately 600 J, duration approximately 10(exp -3) s, density of luminosity was approximately 5 x 10(exp 6) W/sq cm, the temperature of vaporization is about 3000-4000 K. About 4 cm from the sample, a nickel foil was placed on which the condensate was collected. Films of condensate were analyzed using X-Ray Photo-Electron spectrometer ES-2401. The measurement of internal chemical composition and of the charging state of elements through the whole depth of the condensed films was made layer by layer with argon-ion etching of 200 A of the film per step. Results of this study are given. The bottom layers of condensed film correspond to the front parts of the evaporated cloud or to condensation at the beginning of the evaporative process and surface layers to condensation at the end of the process. A CM CHONDRITE CLUSTER AND CM STREAMS Abstract Only c90

R. T. Dodd and M. E. Lipschutz (Purdue Univ., West Lafayette, IN.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 405-406 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

An elongate year-day concentration of CM meteoroid falls between 1921 and 1969 is inconsistent with a random flux of CM meteoroids and suggests that most or all such meteorites, and perhaps the Kaidun C-E chondrite breccia, resulted from streams of meteoroids in nearly circular, Earth-like orbits. To establish whether the post-1920 cluster might have arisen from random sampling, we determined the year-day distribution of 14 falls between 1879 and 1969 by treating each as the corner of a cell of specified dimensions (e.g. 30 years x 30 days) and calculated how many falls occurred in that cell. We then compared the CM cell distribution with random distributions over the same range of years. The results show that for 30 x 30 and 45 x 45 cells, fewer than 5 percent of random sets match the CM distribution with respect to maximum cell content and number of one-fall cells. Author (revised)

RELATION BETWEEN AGES AND ELEVATIONS OF MARTIAN CHANNELS Abstract Only
James M. Dohm and David H. Scott *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 407-408 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Mapping highland and lowland channels and reassessing their time-stratigraphic positions shows that many channels in the cratered highlands are younger than Noachian, that all channels in the lowland plains are Hesperian or younger, and that although Martian channels formed throughout the planet's history, the rate of their formation appears to have declined with time. This detailed examination of the age relation between Martian terrains and the channels that transect them was made possible by the completion of the global geologic maps of Mars and the availability of other geologic maps at scales of 1:5,000,000, 1:2,000,000, and 1:500,000. The present study focuses on the sources (heads) of the channels of the initial study to see if there is a relation between channel age and elevation. Author (revised)

DOES THE THERMAL WIND EXIST NEAR THE EARTH'S CORE BOUNDARY? Abstract Only **c46**
A. Z. Dolginov *In its* Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 409-410 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Temperature distribution in the Earth core determines many important processes such as the following: convective motion, magnetic field generation, matter exchange between the core and the mantle, and the thermal flux. This distribution depends on conditions in the core-mantle boundary and on the distribution of the thermal conductivity in the mantle. Seismic tomography shows that large horizontal temperature and compositional gradients exists at the core-mantle boundary. The simple assumption that these inhomogeneities are extended into the top of the core contradicts the common opinion that the horizontal temperature gradient (the thermal wind) wipes them out in a short time. However, this conclusion has been obtained without taking into account that the core volume is closed and the motion, if it is started, can lead to a small redistribution of composition that stops this motion. MAGNETIC FIELDS AND NONUNIFORM STRUCTURES OF THE MOON Abstract Only
A. Z. Dolginov *In its* Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 411-412 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Direct magnetic measurements performed by space probes demonstrated the existence of small-scale, stationary surface magnetic fields on the Moon. The magnetic field averaged over a region of approximately 600 km was found to be no larger than approximately 10(exp -5) G, that of the regions approximately 100-200 km is approximately 10(exp -5) to 10(exp -4) G, and that of approximately 10-100 km reaches approximately 10(exp -3) G. Investigations of certain lunar rocks reveal stable residual magnetization, which could have been acquired during the crystallization of the rocks in the presence of the outer magnetic field, provided such a field existed at the initial stage of lunar evolution. Estimates show that 4 x 10(exp 9) yr ago the field was small, then it rose to approximately 1.3 G at the beginning of 3.9 x 10(exp 9) yr with a subsequent exponential decrease during the period of 3.9 x 10(exp 9) yr to 3.2 x 10(exp 9) yr ago. Small-scale fields have been explained by some authors as due to mechanical impacts produced by meteors. The theory of this effect is not elaborated in detail. This can in no way explain the paleomagnetic data. These data are commonly explained as a result of the dynamo action in the liquid lunar core. Author (revised)

There is evidence that the terrestrial magnetic field is connected with the Earth's mantle: (1) there are magnetic anomalies that do not take part in the westward drift of the main field, but are fixed with respect to the mantle; (2) the geomagnetic pole position flips in a particular way by preferred meridional paths during a reversal; and (3) magnetic polarity reversals are correlated with the activations of geological processes. These facts may be explained if we take into account that a significant horizontal temperature gradient can exist in the top levels of the liquid core because of the different thermoconductivity of the different areas of the core-mantle boundary. These temperature inhomogeneities can penetrate the core because fluxes along the core boundary (the thermal wind) can be strongly suppressed by a small redistribution of the chemical composition in the top of the core. The nonparallel gradients of the temperature, density, and composition on the top of the core create a curled electric field that produces a current and a magnetic field. This seed-field can be amplified by motions in the core. The resulting field does not forget the seed-field distribution and in this way the field on the Earth surface (that can be created only in regions with high conductivity, i.e. in the core) is connected with the core-mantle boundary. Contrary to the usual approach to the dynamo problem, we will take into account that the seed field of thermoelectric origin is acting not only at some initial moment of time but permanently. ARE COSMIC RAYS EFFECTIVE FOR IONIZATION OF THE SOLAR NEBULA? Abstract Only **c92**
A. Z. Dolginov and T. F. Stepinski *In its* Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 415-416 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

In this paper, we argue that the effectiveness of cosmic rays to ionize the bulk of the nebular gas may be further impaired by the influence of the magnetic field on the propagation of cosmic rays. When cosmic rays enter the nebular disk they ionize the gas and make the dynamo generation of magnetic fields possible. However, once magnetic fields are embedded in the nebular gas, the upcoming cosmic rays can no longer penetrate directly into the nebular disk because they start to interact with the magnetic field and lose their energy before propagating significantly toward the midplane. That, in turn, undercuts the ionization source within the bulk of the gas stopping the dynamo action. Nebular dynamo models ignored this back reaction of magnetic fields on cosmic rays. We calculate this back reaction effect, but for the sake of mathematical simplicity, we ignore the effect of magnetic field weakening due to diminishing ionization by cosmic rays. Author (revised)

ON THE UNIQUE STRUCTURE OF THE MAGNETIC FIELDS OF URANUS AND NEPTUNE Abstract Only
Sh. Sh. Dolginov *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 417-418 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The magnetic fields of Uranus and Neptune, which have comparable dipole, quadrupole, and octupole harmonics, are unique in the present-day solar system, but they resemble the geomagnetic field at the epochs of excursions and reversals known from paleomagnetic data. The precession dynamo model, in which the dominant role in the generation of the planetary magnetic fields is played by external gravitational forces, allows us to propose two scenarios for the formation of the unique topology of the magnetic fields of Uranus and Neptune. In the first case, tidal flows in the 'oceans' of these two planets extend down to the depths where the matter has a noticeable electric conductivity and velocity. A hydromagnetic interaction of the moving conducting fluid with the planetary magnetic field outside the generation region results in the deformation of the field and the deceleration of the motion under the action of the radial magnetic field. In the second case, the deformation of the field facilitates drastic changes in cyclonic cells within the generation region causing instabilities that result in a multi-polar field structure, excursions, and inversions. This paper considers this problem in greater detail by using the Neptune-Triton system as an example. Author (revised)

The strength of the dipole magnetic field of a planet, H(sub p), can be estimated relative to that of the Earth at the epoch of the observation. The generation of magnetic fields in Uranus and Neptune occurs at very different depths for different values of sigma. This assertion is confirmed by the estimation of the Reynolds number (R(sub m)) and agrees with the difference of the contributions of the Joule heat losses into the observed heat fluxes of Uranus and Neptune. Telescopic optical polarimetry over the planet Mars enables us to detect and localize scatterers in the Martian atmosphere. Polarization discriminates between crystal clouds and dust particles. For dust grains, sizes can be derived. There is an increase in size from very small grains forming the permanent dust haze to sub-micrometer size grains for the local dust veils and the several micrometer size pieces found in the dust storm clouds. From all these polarimetric results, an overview emerges about the behavior of dust particles in the Martian atmosphere. Author (revised)

Silicon monoxide is one of the major gas phase silicon bearing components observed in astronomical environments. Silicon oxide serves as the major rock forming material for terrestrial and meteoritic bodies. It is known that several gas phase reactions produce mass independent isotopic fractionations which possess the same delta(O-17)/delta(O-18) ratio observed in Allende inclusions. The general symmetry dependence of the chemically produced mass independent isotopic fractionation process suggests that there are several plausible reactions which could occur in the early solar system which may lead to production of the observed meteoritic oxygen isotopic anomalies. An important component in exploring the role of such processes is the need to experimentally determine the isotopic fractionations for specific reactions of relevance to the early solar system. It has already been demonstrated that atomic oxygen reaction with CO, a major nebular oxygen bearing species, produces a large (approximately 90 percent), mass independent isotopic fractionation. The next hurdle regarding assessing the involvement of symmetry dependent isotopic fractionation processes in the pre-solar nebula is to determine isotopic fractionation factors associated with gas phase reactions of metallic oxides. In particular, a reaction such as O + SiO yields SiO2 is a plausible nebular reaction which could produce a delta(O-17) is approximately delta(O-18) fractionation based upon molecular symmetry considerations. While the isotopic fractionations during silicate evaporation and condensation have been determined, there are no isotopic studies of controlled, gas phase nucleation processes. In order to carefully control the reaction kinetics, a molecular beam apparatus has been constructed. This system produces a supersonic, collimated beam of SiO molecules which is reacted with a second beam of oxygen atoms. An important feature of molecular beams is that they operate at sufficiently low pressures and high temperatures in the jet that avalanche nucleation and clustering processes may be avoided. ON HIGH-TEMPERATURE FORMATION OF IRON-RICH OLIVINE IN THE EARLY SOLAR SYSTEM Abstract Only **c90**
V. A. Dorofeyeva, A. B. Makalkin, and A. V. Vityazev *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 425-426 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

A kinetic restriction on the formation of fayalite-rich olivine in equilibrium with the cooling solar-composition gas appears to exist at the low temperature of approximately 500 K. We offer a high-temperature formation mechanism (different from simple condensation) which operates at high hydrogen depletion (up to 300 times) relative to solar abundance. We show how the necessary depletion rate decreases with temperature (thermodynamical equilibrium is suggested). The consequences for planet formation are considered. Author (revised)

RECONDENSATION OF CHONDRITIC MATERIAL IN THE EARLY SOLAR SYSTEM: RESULTS OF THERMODYNAMIC SIMULATION Abstract Only **c90**
V. A. Dorofeyeva, A. B. Makalkin, M. V. Mironenko, and A. V. Vityazev *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 427-428 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

We have performed a thermodynamic simulation of the recondensation of evaporated meteoritic material. We suggest that evaporation and recondensation occurred in impact events during the intercollision of planetesimals during the early evolution of the solar system. The source materials adopted for our model are the chondrites CI Orgueil and H5 Richardton. These chondrites are representative examples of the two extremes regarding volatile content and oxidation state. We calculated equilibrium mineral compositions of the closed systems of the Orgueil's and Richardton's elemental composition at the P-T conditions characteristic of the explosion cloud formed at a planetesimal collision. The P-T conditions are as follows: 10(exp -4) bar, and 1500 and 2000 K. The results are presented. Author (revised)

ANALYTIC EXPRESSION FOR EPITHERMAL NEUTRON SPECTRA AMPLITUDES AS A FUNCTION OF WATER CONTENT Abstract Only
Darrell Drake *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 429-430 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The epithermal portion of an equilibrium neutron spectrum in a planetary body is a function of the water content of its material. The neutrons are produced at high energies but are moderated by elastic and inelastic scattering until they either are captured by surrounding nuclei or escape. We have derived an expression that explicitly shows the dependance of epithermal neutron spectra on water content. Additionally, we compared its predictions to calculations done by Boltzman transport code for infinite media for silicon, oxygen, and a possible lunar composition, and we have obtained very good agreement. NOBLE GAS EVIDENCE OF AN AQUEOUS RESERVOIR NEAR THE SURFACE OF MARS MORE RECENTLY THAN 1.3 Ga Abstract Only

Michael J. Drake, Toby Owen (Hawaii Univ., Manoa.), Timothy Swindle, and Donald Musselwhite *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 431-432 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Considerable evidence points to a Martian origin of the SNC meteorites. One of these meteorites, Nakhla, contains a leachable component which has an elevated Xe-129/Xe-132 ratio relative to its Kr-84/Xe-132 ratio when compared to the approximately linear array defined by Chassigny, most shergottites, and lithology C of EETA 79001. This array is thought to be a mixing line between Martian mantle and Martian atmosphere. The leachable component probably consists in part of iddingsite, an alteration product produced by interaction of olivine with aqueous fluid at temperatures lower than 150 C. The radiogenic Xe component may represent a distinct reservoir in the Martian crust or mantle. More plausibly, it is Martian atmosphere, fractionated by solution in liquid water and by interaction with sediment. The crystallization age of Nakhla is 1.3 Ga. Its low shock state suggests that it was ejected from near the surface of Mars. Liquid water is required for the formation of iddingsite. These observations provide further evidence for the near surface existence of aqueous fluids more recently than 1.3 Ga. Author (revised)

EXPLORATION PLANNING IN THE CONTEXT OF HUMAN EXPLORATION AND DEVELOPMENT OF THE MOON Abstract Only
Michael B. Duke and Donald A. Morrison *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 433 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

It is widely believed that the next step beyond low Earth orbit in attaining the United States' stated goal of 'Expanding human presence beyond the Earth' should be to reestablish a lunar capability, building on the Apollo program, and preparing the way for eventual human missions to Mars. The Moon offers important questions in planetary and Earth science, can provide a unique platform for making astronomical observations of high resolution and sensitivity, and can be in the development path for unlocking resources of the inner solar system to support space activities and return benefits to Earth. NASA's Office of Exploration has undertaken the planning of future lunar exploration missions with the assistance of the Solar System Exploration Division in matters dealing with the quality of scientific data and the manner in which it will be made available to the scientific community. The initial elements of the proposed program include the Lunar Scout missions, which consist of two small identical spacecraft in polar orbit around the Moon, which can accomplish most of the objectives associated with previous proposals for Lunar Polar Orbiters. These missions would be followed by 'Artemis' landers, capable of emplacing up to 200 kg payloads anywhere on the Moon. In addition, the exploration program must incorporate data obtained from other missions, including the Galileo lunar flybys, the Clementine high orbital observations, and Japanese penetrator missions. In the past year, a rather detailed plan for a 'First Lunar Outpost (FLO)' which would place 4 astronauts on the lunar surface for 45 days has been developed as a possible initial step of a renewed human exploration program. In the coming year, the FLO concept will be reviewed and evolved to become more highly integrated with planning for the initial human exploration of Mars, which could come perhaps 5 years after the reestablishment of lunar capability. Both programs could benefit from the common development of systems and subsystems, where that is sensible from a performance perspective. Author (revised)

PRIMORDIAL LIGHTNING: EVIDENCE PRESERVED IN CHONDRITES Abstract Only **c90**
D. Eisenhour and P. R. Buseck *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 435-436 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

An increasing body of evidence suggests that transient heating events were important in forming or modifying many constituents of chondritic meteorites. For example, chondrule compositions and textures imply high cooling rates (approximately 5 to greater than 2000 C/hr) with only limited exposure to elevated temperatures (greater than 1200 C). Similarly, experimental studies of CAI's exhibiting igneous textures suggest cooling rates from 0.5 to 1000 C/hr, and thermal pulses as short as milliseconds may be responsible for CAI rim formation. Additionally, the spectrum of organic compounds observed in chondrites suggests that transient heating may also have played an important role in their formation. The exact nature of these transient events is less clear. A variety of mechanisms have been proposed (e.g., shock melting, drag heating, volcanism, electric discharges, and magnetic reconnection). However, a consensus is lacking as to which or what combination of these mechanisms was responsible for the range of features we observe in chondrites today. Much of the difficulty lies in the inability to identify features unique to any given process. Here we discuss electric discharges ('lightning') as a transient heat source and describe its unique signature preserved in chondrites.

Avail: CASI HC A01/MF A06

There is an increasing number of meteorites with chondritic bulk composition but completely different textures than the conventional chondrite groups. Winonaites, Acapulcoites and silicate inclusions in IAB-iron meteorites have in common coarse grain size, highly equilibrated mineralogy with frequent 120 deg triple junctions and they record a significantly lower degree of oxidation than ordinary chondrites. They all have equilibration temperatures, based on Ca-exchange among pyroxenes, of around 900 to 1100 deg C. However, on cooling disequilibrium features may develop: (1) Olivine in IAB-inclusions has lower Fa-content than equilibrium Fs-content of pyroxenes requires; (2) CaO-zoning in olivine was established at temperatures of around 500 deg C, several hundred degrees below pyroxene equilibration temperatures. Obviously, olivine responded faster to changes in fO2 (Fa in olivine) and temperature (Ca-zoning) than pyroxenes. Differences in diffusion coefficients can readily explain the observed trends. Here we report on much more subtle zoning features in pyroxenes. TEM-observations reveal large compositional gradients in Ca, Na, Cr, Ti and Fe within the first micrometer of cpx and opx crystals. In summary, the data reflect the complicated subsolidus history of a chondritic mineral assemblage that was in thermodynamic equilibrium at about 900 deg C and cooled slowly from this temperature whereby oxidation reactions and different closure temperatures for various minerals and elements played an important role. The oxidation of P dissolved in metal and formation of phosphate, which is thermodynamically stable at low temperatures, is suggested to be responsible for most of the observed zoning.

SOLAR WIND-INDUCED SECONDARY IONS AND THEIR RELATION TO LUNAR SURFACE COMPOSITION Abstract Only **c92**
R. C. Elphic, H. O Funsten, III, and R. L. Hervig (Arizona State Univ., Tempe.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 439 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Based on previous laboratory experiments simulating solar wind sputtering of lunar surface materials, it appears that solar wind ions sputter secondary ions in sufficient numbers to be measured from low-altitude lunar orbit. Solar wind protons are hundreds of times less efficient than those used in standard secondary ion mass spectrometry; nevertheless secondary ions of Na, Mg, Al, Si, K, Ca, Mn, Ti and Fe were observed sputtered from sample simulants of mare and highland soils. These secondary ion fluxes depend both on concentration in the soil and on probability of ionization; yields of easily ionized elements such as K and Na are relatively much greater than those for the more electronegative elements and compounds. The principal geochemical indicator elements

Na, Mg, Al, Si, K, Ca, Ti, Mn and Fe are nevertheless detectable. However, it has not been shown that the observed secondary ions vary strictly one-to-one with their concentrations in the geochemically distinct soil simulants used here. While we have a first order understanding of secondary ion sputtering, it is not clear that the observed ion yields can be linked with great accuracy to the simulant's composition. The simulants were analyzed by electron microprobe to establish their detailed composition. The observed secondary ion fluxes can then be compared with the microprobe results. For example Ti(+) fluxes from the three simulants correspond to the true composition with accuracies of better than 10 percent for the high-Ti basalt, and about 20 percent for the low-Ti simulant. The highlands simulant produced a statistically insignificant Ti(+) count rate. Here we discuss the results of further SIMS experiments using the ASU/Center for Solid State Science facility. With careful isolation and preparation of samples, we avoid the problems of the previous experiments. In particular, we will make use of ground-up sample to mimic the sputtering behavior of regolith, and will avoid charging by placing the soil on a conducting indium substrate. We report the results of a blind test of the SIMS technique using a sample of unknown composition. Author (revised)

A NEW CARBON-RICH PHASE (COPS) IN ANTARCTIC MICROMETEORITES Abstract Only **c90**

C. Engrand, M. Maurette, G. Kurat (Naturhistorisches Museum, Vienna, Austria.), F. Brandstatter (Naturhistorisches Museum, Vienna, Austria.), and M. Perreau (Office National d'Etudes et de Recherches Aeronautiques, Paris, France.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 441-442 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

The contemporary flux of micrometeorites with sizes greater than 50 microns reaching the Earth's surface each year (about 20,000 tons/a) is much greater than the value of approximately 100 tons/a reported for conventional meteorites up to masses of approximately 10,000 tons. Moreover, on the average, Antarctic micrometeorites contain at least as much carbon as does Orgueil, the most C-rich meteorite. Micrometeorites are thus responsible for most of the carbon accreted by the Earth. In this paper we report SEM observations of a new C-rich 'dirty magnetite' phase observed as tiny inclusions in both melted and unmelted micrometeorites. This phase, which is enriched in C, O, P, S, Fe, frequently shows Ni contents in excess of 0.2 percent, strongly suggestive of an 'extraterrestrial' origin. We also discovered this 'COPS' phase in the fusion crust of Murchison. It appears likely that COPS is a product of meteoroid reprocessing during frictional heating in the Earth's atmosphere and/or its fast 'weathering' in the upper atmosphere. Upon 'catalyzed' hydrolysis this phase might have facilitated the functioning of micrometeorites as 'micro-chondritic-reactors' for the synthesis of prebiotic molecules on the early Earth. AUTOMATIC DEFINITION OF SPECTRAL UNITS IN THE EQUATORIAL REGIONS OF MARS Abstract Only **c90**

Stephane Erard, Priscilla Cerroni, and Angioletta Coradini *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 443-444 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

ISM was the first instrument that acquired spectra of small areas (25x25 sq km) on a planetary surface. The data set consists mainly in images made up of about 3000 such pixels, each one corresponding to a near-infrared spectrum (0.76 to 3.15 microns in 128 spectral channels) with high signal-to-noise ratio. These data were used to define spectral units and to constrain the mineralogy of surface materials in the equatorial regions of the planet. Future spaceborne imaging spectrometers (e.g. OMEGA on board the Mars-94 Russian spacecraft) are expected to provide several hundred times as much data as ISM, so there's a strong need for fast and reliable processing methods. The present work is an attempt to define spectral units in the region of Syrtis Major-Isidis Planitia by means of G-mode analysis. The method allows to cluster the spectra according to their similarities; different levels of classification can be achieved by tuning a threshold of confidence. Derived from text

COMPOSITION OF THE MARTIAN AEROSOLS THROUGH NEAR-IR SPECTROSCOPY Abstract Only

Stephane Erard, Priscilla Cerroni, and Angioletta Coradini *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 445-446 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Near-infrared spectroscopy is a powerful technique to study the composition of planetary surfaces, as the main minerals exhibit absorption bands in this spectral range. It gave important information on the mineralogy and petrology of Mars in the past twenty years although in this case it is well known that a large fraction of light is scattered by the airborne particles before reaching the surface. The measured signal is thus the sum of two different contributions that should be studied separately: One from the surface and one from the aerosols that depends on their density, size distribution and composition. Data from the ISM imaging spectrometer are used here to derive the aerosols spectrum. They consist in sets of spectra (from 0.76 to 3.16 microns) of approximately 3000 pixels approximately 25x25 sq km in size. The resulting spectrum exhibits both water-ice and clay mineral features superimposed on a scattering continuum. Derived from text

GIANT RADIATING DYKE SWARMS ON EARTH AND VENUS Abstract Only **c46**

Richard E. Ernst, James W. Head (Brown Univ., Providence, RI.), Elisabeth Parfitt (Brown Univ., Providence, RI.), Lionel Wilson (Brown Univ., Providence, RI.), and Eric Grosfils (Brown Univ., Providence, RI.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 447-448 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

On Earth, giant radiating dyke swarms are usually preserved as fan-shaped fragments which have been dismembered from their original configuration by subsequent plate tectonic rifting events. Analysis of the largest fragments and consideration of their original configuration has led to the idea that many swarms are plume related, and that dyke swarms radiate away from plume centers. Magellan radar data reveal abundant intact giant radiating swarms on Venus which are similar in scale and pattern to those on Earth. The absence of intense weathering and plate tectonic processes on Venus accounts for the preservation of the primary radiating patterns. It is characteristic of both Earth and Venus that giant radiating dikes are emplaced laterally for distances of at least 2000 km away from plume centers. At distances beyond the influence of the plume on both Earth and Venus, the radiating dyke pattern is often swept into a linear pattern aligned with the regional stress field. There is tremendous potential synergism between the characterization and analysis of terrestrial dyke swarms (where significant erosion has revealed their structure and emplacement directions at depth) and the giant swarms of Venus (where the complete circumferential structure is preserved, and the surface fracture systems above near surface dikes and the nature of the central source regions are revealed). In this study, we report on the characteristics of radial dyke swarms on Earth and Venus and draw some preliminary comparisons from the two perspectives. In summary, on both planets there is evidence for plume-related magmatic centers associated with vertical and lateral injection of magma over considerable distances (up to at least 2000 km). The abundance of very broadly radiating swarms on Venus supports the notion that the swarms on Earth were radiating over broad sectors at the time of intrusion but were dissected by later events. The Venus data show that a swarm can change from radiating (proximal) to regional (distal) subparallel orientations. An implication for Earth is that many regional linear swarms which do not have a radiating pattern may be due to fragmentation of the swarm during later plate tectonic rifting. Completion of the global classification and census of Venus features, comparison to the terrestrial synthesis, and documentation of the mode of emplacement of dikes in these environments (buffered and unbuffered conditions) should lead to additional general insight into mechanisms of formation and evolution and their relation to plumes. Re-Os DATING OF 3AB IRON METEORITES Abstract Only **c90**

Tezer M. Esat and Victoria Bennett *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 449-450 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Recently, Creaser et al., and Volkening and Heumann, have demonstrated the efficient production of large (approximately 10 exp -11 A) ion beams by negative thermal ionization mass spectrometry (NTIMS) using standard laboratory solutions of Os compounds. Horan et al., have applied NTIMS to a group of 7 IIA iron meteorites and obtained a Re-Os closure age of 4596 +/- 152 million years. The initial Os-187/Os-186 ratio was 0.8007 plus or minus 0.0029. In addition they analyzed 3 IIIA meteorite samples which indicated an age of 4554 +/- 180 million years and Os initial of 0.8120 +/- 0.0075 which does not overlap with the initial for the IIA irons. We have been independently pursuing a similar program with the direct aim of determining possible variations in the initial (Os-187)/(Os-186) ratio or Re-Os closure age of different classes of iron meteorite. We have applied NTIMS to Os extracted from the most common group of iron meteorites the IIIAB. These meteorites are believed to be of magmatic origin, formed by fractional crystallization of molten cores of asteroidal bodies. The present results point to a significantly lower initial (Os-187)/(Os-186) ratio of 0.7731 plus or minus 0.0050 than previously determined. Author

MODELLING OF DISPERSAL AND DEPOSITION OF IMPACT GLASS SPHERULES FROM THE CRETACEOUS-TERTIARY BOUNDARY DEPOSIT Abstract Only **c90**

J. M. Espindola, S. Carey (Rhode Island Univ., Narragansett.), and H. Sigurdsson (Rhode Island Univ., Narragansett.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 451-452 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

The dispersal of glass spherules or tektites from a bolide impact with the Earth is modelled as ballistic trajectories in standard atmosphere. Ballistic dispersal of Cretaceous-Tertiary boundary impact glass spherules found in Haiti and Mimbral, Mexico requires a fireball radius in excess of 50 km but less than 100 km to account for the observed distribution. Glass spherules from 1 and up to 8 mm in diameter have been found at the KT boundary at Beloc in Haiti, at Mimbral, Mexico, and at DSDP Sites 536 and 540 in the Gulf of Mexico corresponding to paleodistances of 600 to 1000 km from the Chicxulub crater. In Haiti the basal and major glass-bearing unit at the KT boundary is attributed to fallout on basis of sedimentologic features. When compared with theoretical and observed dispersal of volcanic ejecta, the grain size versus distance relationship of the KT boundary tektite fallout is extreme, and rules out a volcanic fallout origin. At a comparable distance from source, the KT impact glass spherules are more than an order of mangitude coarser than ejecta of the largest known volcanic events. We model the dispersal of KT boundary impact glass spherules as ballistic ejecta from a fireball generated by the impact of a 10 km diameter bolide. Mass of ejecta in the fireball is taken as twice the bolide mass. Melt droplets are accelerated by gas flow in the fireball cloud, and leave the fireball on ballistic trajectories within the atmosphere, subject to drag, depending on angle of ejection and altitude. The model for ballistic dispersal is based on equations of motion, drag and ablation for silicate spheres in standard atmosphere. Author

THE Xe-Q IN LODRANITES AND A HINT FOR Xe-L. FRO90011 ANOTHER LODRANITE? Abstract Only **c90**

O. Eugster and A. Weigel *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 453-454 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

The Lodran achondrite contains about one-quarter metallic Fe/Ni, two-thirds olivine and pyroxene, some troilite, plus minor phases. In a previous study we demonstrated that Lodran and three other lodranites - LEW88280, Yamato-791491, and MAC88177 - yield the same cosmic-ray exposure age of a few million years, suggesting that they originate from the same parent body. In the present work we show that the mineral phases of Lodran contain large concentrations of planetary-type but no solar-type trapped noble gases. Surprisingly, the highest concentrations were observed in the Fe/Ni-phase (e.g. 1520 x 10(exp -12) cc STP per g (132)Xe). A large fraction of the trapped gas is released between 1200 C and 1400 C. The Xe isotopic pattern is similar to that of Xe-Q. The 1400 C fraction of the Fe/Ni-phase shows excesses of (124)Xe, (126)Xe, and (128)Xe similar to Xe-L (pre-solar Xe enriched in the light isotopes) that has, until now, only been observed in combination with Xe-H (pre-solar Xe enriched in the heavy isotopes). ON THE ORIGIN OF (4)He AND (40)Ar IN NATURAL GOLD Abstract Only **c26**

O. Eugster, B. Hofmann, S. Niedermann, and Ch. Thalmann *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 455-456 (SEE N94-12015 01-91) 1993 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

In a first report on our investigations of noble gases in native gold we demonstrated that placer gold contains an excess of radiogenic (4)He and (40)Ar relative to the concentrations expected from in situ decay of U, Th, and K, respectively, during the geologic age of about 30 Ma of the samples. We also showed that the U/Th-(4)He age of 36 Ma of vein-type gold from the Southern Alps agrees with its K-Ar formation age derived from associated muscovite and biotite. We now studied the question of the origin of the (4)He and (40)Ar excesses of placer gold. We conclude that gold contains two components of noble gases, a low-temperature component from fluid inclusions or phases which release noble gases at less than 800 C and a high-temperature component released when gold melts (1064 C). In some samples extremely high U and K concentrations or an unreasonably high formation age would be required to explain the observed (4)He abundances. Thus, trapped (4)He and (40)Ar must be present in gold. Author

PROJECTILE-TARGET MIXING IN MELTED EJECTA FORMED DURING A HYPERVELOCITY IMPACT CRATERING EVENT Abstract Only **c90**

Noreen Joyce Evans, Thomas J. Ahrens, M. Shahinpoor, and W. W. Anderson *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 457-458 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Tektites contain little to no projectile contamination while, in contrast, some distal ejecta deposits can be relatively projectile-rich (e.g. the Cretaceous-Tertiary (K-T) boundary clay). This compositional difference motivated an experimental study of hypervelocity target-projectile mixing processes. We hope to scale up the results from these experiments and apply them to terrestrial impact structures like the Chicxulub Crater, Yucutan, Mexico, the leading contender as the site for the impact that caused the mass extinction that marks the K-T boundary. Shock decomposition of the approximately 500m thickness of anhydrite, or greater thickness of limestone, in the target rocks at Chicxulub may have been a critical mechanism for either global cooling via SO3, and subsequently H2SO4, formation, or possibly, global warming via increased CO2 formation. Understanding target-projectile mixing processes during hypervelocity impact may permit more accurate estimates of the amount of potentially toxic, target-derived material reaching stratospheric heights. Avail: CASI HC A01/MF A06

Development of space rocketry and cosmic instrument making has made it possible to create interplanetary stations to be sent to the solar system bodies. In the last decade of the century the planet Mars will be in the focus of planetary science problems. Russia, USA (the NASA) and Europe (the ESA) plan to do a new step in the study of the planetary system by spacecraft missions to Mars. One part of the programs of these missions is Martian surface measurements of iron, which is a dominant element in both the Martian soil and rocks (about 13 percent by weight). The chemistry of iron in space is strongly coupled to the chemistry of abundant elements (to begin with hydrogen, carbon, oxygen) and it is this coupling of chemical cycles of abundant elements that gives us the possibility of understanding some features of the chemical evolution of matter. In this connection of extremely great importance for the understanding of the evolution of the solar system are the oxidation state of the iron and its mineral composition of the Mars surface. Being highly successful, the Viking landers had no instrumentation to answer these questions. Such instrumentation has to be specifically sensitive to mineralogy. For this purpose the back scattering Moessbauer spectrometer (MS-96) was proposed to be installed on a rover to be launched on board the Russian spacecraft Mars-96 mission to Mars. Due to power and mass restrictions three systems of the device MS-96 (velocity transducer, detector and electronic components) have been extremely miniaturized in comparison to a standard system. In this paper we intend to place for consideration a radioactive source to find out what characteristics it should have to be suitable for purposes of the experiment. Author (trans.)

VULCANIAN EXPLOSIVE ERUPTIONS: A MECHANISM FOR LOCALISED PYROCLAST DISPERSAL ON VENUS Abstract Only
S. A. Fagents and L. Wilson *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 461-462 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

A model of the mechanisms involved in transient (vulcanian-type) explosive eruptions has enabled us to place constraints on the velocities of blocks ejected during such events on Earth as well as on the excess pressure and concentration of gas in the vent prior to the onset of the explosion. This model, suitably modified, can predict the results of similar eruptions occurring under the differing Venusian environmental conditions. It is found that the much higher atmospheric pressure (approximately 100 bars at the mean planetary radius) dominates the form of the resulting deposit in two main ways: (1) by inhibiting the expansion out of the vent of overpressured gas, hence reducing ejecta velocity; and (2) by retarding the flight of ejected blocks via drag effects. Thus, it is expected that such deposits will typically extend to approximately 200 m on Venus as compared to several km for documented terrestrial deposits. Author

CHONDRITES, S ASTEROIDS, AND SPACE WEATHERING: THUMPING NOISES FROM THE COFFIN? Abstract Only **c90**
F. P. Fanale and B. E. Clark *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 463-464 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Most of the spectral characteristics of ordinary chondrites and S-asteroids in the visible and infrared can be reduced to three numerical values. These values represent the depth of the absorption band resulting from octahedrally coordinated Fe(sup 2+), the reflectance at 0.56 microns and the slope of the continuum (as measured according to convention). By plotting these three characteristics, it is possible to immediately compare the spectral characteristics of large numbers of ordinary chondrites and S-asteroids. Commonality of spectral characteristics between these populations can thus be evaluated on the basis of overlap in position on three two-coordinate systems: albedo vs. band depth, band depth vs. slope, and slope vs. albedo. In order to establish identity, members of the two populations must overlap on all three of these independent parameter spaces. In this coordinate system, spectra of 23 ordinary chondrites (representing all metamorphic grades), and 39 S-asteroids were compared. It was found that there was no overlap between the two populations in terms of the slope vs. band depth parameters, nor were most chondrites identical to the S-asteroids with respect to the other criteria. However, the controversial question remains: Where are the parent bodies of the chondrites? Perhaps an even more critical question is: Where are our samples of the S-asteroids? Considering the geography of the asteroid belt and the theory that early solar-system electromagnetic induction heating differentiated protoasteroids in the inner portion of the main belt, it was suggested that although S-asteroids and ordinary chondrites have very similar mineralogy, the S-asteroids are mixtures of metallic nickel iron and silicates which resulted from magmatism induced by electromagnetic heating whereas chondrites were only slightly metamorphosed nebular condensates. In this scenario chondrites would have been derived from a population of bodies with thermal lag times so short that they were not subjected to melting during the phase of the electromagnetic induction heating event but only to various degrees of pervasive metamorphism. Furthermore, these objects would then have been too small to be observed and systematically included in the library of asteroidal spectra. It was also suggested that the parametric distribution of S-asteroid spectra could be reproduced by mixing various proportions of NiFe meteorite and achondritic materials. This has also been demonstrated in the laboratory. Author

A COMPARISON OF THE VISIBLE AND NEAR INFRARED REFLECTANCE OF HYDROVOLCANIC PALAGONITE TUFFS AND MARTIAN WEATHERED SOILS Abstract Only
W. H. Farrand and R. B. Singer (Arizona Univ., Tucson.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 465-466 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The visible and near infrared reflectance of Martian weathered soils, abundant in the bright regions, have been shown to resemble certain examples of the X-ray amorphous mineraloid palagonite. To date, most comparisons between terrestrial palagonites and Martian telescopic spectra have been done using palagonites that were formed under ambient semi-arid weathering conditions on Hawaiian volcanoes such as Mauna Kea. Here we examine palagonites associated with the tephra deposits that make up tuff rings and tuff cones. Tuff rings and tuff cones result from hydrovolcanic activity, defined as the interaction of magmas (in this instance, of basaltic composition) with surface or near-surface water. Tuff rings and tuff cones can contain variable amounts of country rock and juvenile crystals, but their primary constituent is fine grained sideromelane (basaltic glass). Sideromelane alters to palagonite. Unlike the aforementioned Hawaiian palagonites, the alteration of sideromelane to palagonite seems to occur relatively rapidly in tuff cones, on the order of days to months. In comparing the spectra of hydrovolcanically produced palagonites with telescopic spectra of Mars, one is struck by their similarity in the VNIR and dissimilarity in the SWIR. Author

THE RATE OF CHEMICAL WEATHERING OF PYRITE ON THE SURFACE OF VENUS Abstract Only
B. Fegley, Jr. and K. Lodders *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 467-468 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

This abstract reports results of an experimental study of the chemical weathering of pyrite (FeS2) under Venus-like conditions. This work, which extends the earlier study by Fegley and Treiman, is part of a long range research program to experimentally measure the rates of thermochemical gas-solid reactions important in the atmospheric-lithospheric sulfur cycle on Venus. The objectives of this research are (1) to measure the kinetics of thermochemical gas-solid reactions responsible for both the production (e.g., anhydrite formation) and destruction (e.g., pyrrhotite oxidation) of sulfur-bearing minerals on the surface of Venus and (2) to incorporate these and other constraints into holistic models of the chemical interactions between the atmosphere and surface of Venus. Experiments were done with single crystal cubes of natural pyrite (Navajun, Logrono, Spain) that were cut and polished into slices of known weight and surface area. The slices were isothermally heated at atmospheric pressure in 99.99 percent CO2 (Coleman Instrument Grade) at either 412 C (685 K) or 465 C (738 K) for time periods up to 10 days. These two isotherms correspond to temperatures at about 6 km and 0 km altitude, respectively, on Venus. The reaction rate was determined by measuring the weight loss of the reacted slices after removal from the furnace. The reaction products were characterized by X-ray diffraction, scanning electron microscopy, and energy dispersive spectroscopy on the SEM. Author

TERRESTRIAL CASE STUDIES OF ILMENITE EXPLORATION AND LUNAR IMPLICATIONS Abstract Only

S. C. Feldman and H. A. Franklin *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 469-470 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

The Space Exploration Initiative (SEI) includes space resource utilization as one of the four architectures to achieve U.S. goals in space. Space resource utilization will make use of lunar resources to support long term activities on the lunar surface. Lunar ilmenite and regolith are two of the materials that can be mined and processed for lunar oxygen production. During this investigation, several sources were reviewed to assess terrestrial exploration methods used for locating ilmenite resources. These sources included published reports on terrestrial ilmenite exploration methods, analytical methods, case histories, chemical and physical properties, and associations with other minerals. Using a terrestrial analog and considering the differences between terrestrial and lunar environmental conditions, rocks, and minerals, exploration methods and analytical instruments can be recommended for a lunar orbiter and lander for assessing lunar resources. Twelve terrestrial case histories were reviewed to gain insight into ilmenite exploration on the Moon. All exploration case histories follow the same pattern. They begin with a model, use remote geophysical techniques, define regional sampling sites from the model and geophysics, narrow down the area of exploration based on the preceding work, collect more samples and cores, and perform laboratory analyses of samples. An important part of this process is the collection of samples to determine the correctness of the model. Surface and core samples are collected in areas expected to contain both high and low concentration of the commodity to test the model. After samples are analyzed and the area of mineralization is defined, reserves are calculated to determine the cost/benefit ratio, the necessary capacity of the processing plant, and the life of the mine. The exploration methods used for locating terrestrial ilmenite resources are reviewed with respect to the petrology, chemistry, and mineral associations of the terrestrial and lunar environments. Venus topography can be mapped morphostructurally to reveal nested hierarchical patterns of quasi-circular upland/lowland complexes. These patterns are interpreted as surficial effects of hierarchically structured, long-acting mantle convection. Beta Regio, Alpha Regio, and Artemis illustrate this process of dynamical interaction between the deforming lithosphere and the convecting mantle. Author

TRANSMANTLE FLUX TECTONICS Abstract Only **c46**

V. J. Finn, A. Z. Dolginov (Lunar and Planetary Inst., Houston, TX.), and V. R. Baker *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 473-474 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Venus, Earth, and Mars have surfaces that display topographic domes and depressions with quasi-circular planimetric shapes, relief of 0 to several km, and large spatial scales (10(exp 2) to 10(exp 4) km). Our morphostructural mapping reveals hierarchical arrangements of these features. They are explained by a model of long-acting mantle convection, as a particular case of convection in a stratified and random inhomogeneous medium, which develops the form of a hierarchy of different convective pattern scales, each arising from different levels in the mantle. The hypothesis of transmantle flux tectonics parsimoniously explains a diversity of seemingly unrelated terrestrial planetary phenomena, including Earth megaplumes, global resurfacing epochs on Venus, and cyclic ocean formation and global climate change for Mars. All these phenomenon are hypothesized to be parsimoniously explained by a process of transmantle flux tectonics in which long-acting mantle convection generates stresses in blocks of planetary lithosphere to produce distinctive quasi-circular global-hierarchical morphostructure (QGM) patterns. Transmantle flux tectonics differs from plume tectonics in that individual plumes are not considered in isolation. Rather, a wholly interactive process is envisioned in which various spatial and temporal scales of convection operate contemporaneously and hierarchically within other scales. This process of continual change by hierarchical convective cells affects the surface at varying temporal and spatial scales, and its effects are discernable through their relic geological manifestations, the QGM patterns. ASSIMILATION IN LUNAR BASALTS AND VOLCANIC GLASSES: IMPLICATIONS FOR A HETEROGENOUS MANTLE SOURCE REGION Abstract Only

A. B. Finnila, P. C. Hess, and M. J. Rutherford *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 475-476 (For primary document see N94-12015 01-91)

Avail: CASI HC A01/MF A06

Several scientists have called on assimilation of anorthositic crustal material or KREEP compositions to explain various lunar lithologies. In order to address the practicality of such processes, some techniques for calculating how much assimilation is possible in magma chambers and dikes based on thermal energy balances and simple fluid mechanical constraints are outlined. In a previous effort, it was demonstrated that dissolution of plagioclase in an iron-free basalt was too slow to contaminate magmas, and that the energy cost of melting plagioclase-rich crustal material was prohibitive both in magma chambers and in dike conduits. This analysis was extended to include dissolution rates in an orange glass composition and to quantitatively predict the maximum contamination possible due to assimilation of both lunar crustal material and KREEP. MEASURING AND DISTINGUISHING COMPOSITIONAL AND MATURITY PROPERTIES OF LUNAR SOILS BY REMOTE VIS-NIR SPECTROSCOPY Abstract Only

Erich M. Fischer and Carle M. Pieters *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 477-478 (SEE N94-12015 01-91) 1993 (For primary document see N94-12015 01-91)

(Grant NAGw-28)

Avail: CASI HC A01/MF A06

Space weathering on the lunar surface affects the spectra/optical character of an exposed lunar soil in three ways: the reflectance is reduced, absorption band depths are reduced, and a red-sloped continuum is created and increased with exposure. As a result, the spectrum of a lunar soil is dependent upon both the degree of exposure at the lunar surface and the original composition. It is critical to the remote analysis of lunar soils to differentiate between the optical effects of maturity and the effects of composition. In the laboratory, it is possible to determine and consequently distinguish the degree of exposure, or soil maturity, as measured by parameters such as I(sub s)/FeO (e.g., 1; mature defined as I(sub s)/FeO greater than or equal to 60), and the composition, as measured by various chemical and petrographical techniques. Lunar soils returned by the Apollo missions provide important ground truth for developing methods for remotely measuring the maturity and the concentration of Fe-bearing minerals in lunar soil. The ground truth spectral data analyzed are from the John Adams lunar soil spectra collection. Soils collected from or near highland terrains are emphasized in the discussion. The mineralogical makeup of mare soils results in behavior somewhat different from highland soils. Author (revised)

DIAMOND THERMOLUMINESCENCE PROPERTIES OF DIFFERENT CHONDRITES Abstract Only **c90**

A. V. Fisenko, L. L. Kashkarov, L. F. Semjonova, and C. T. Pillinger (Open Univ., Milton, England.) *In* Lunar and Planetary Inst., Twenty-fourth

Lunar and Planetary Science Conference. Part 1: A-F 1993 p 479-480 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

It was found that thermoluminescence (TL) glows of diamonds depend on the origin of diamonds and the chondrite metamorphism degree. The investigation of TL of diamonds was continued and the results for diamonds from Murchison CM2, Krymka LL3.0, Kainsaz CO3, and Abee E4 were considered. The diamonds synthesized by CVD-process (samples 133, 159) and by detonation from soot (DDS-B14-89) were also analyzed for comparison. Before the TL measuring samples were annealed at approximately 350 C for a few seconds and then irradiated by gamma-rays of Cs-137 up to dose approximately 200 krad. TL-measurements were performed in the air atmosphere on the standard equipment. TL data for samples are shown. TL glow for some diamonds are also presented. Author (revised)

THE UNUSUAL METALLIC PARTICLES IN KRYMKA LL3.0 CHONDRITE Abstract Only c90

A. V. Fisenko, A. Yu. Ljul, L. F. Semjonova, and K. I. Ignatenko *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 481-482 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The composition, structure peculiarities, and possible scenario of formation of unusual metallic particles in Krymka LL3.0 are shown. In metal released from gentle crushed after removal of chondrules of Krymka LL3.0 chondrite matter, two types of unusual metallic particles were detected. The first type of particle mainly consists of coarse-grained (greater than or equal to 50 microns) kamacite and fine-grained (less than or equal to 10 microns) Ni-high (approximately 53 wt. percent) taenite. These particles have well-defined zonal structure: kamacite is in central part of particles whereas taenite is in outside and the grains of taenite form the mantle around kamacite. In the second type of particle Fe,Ni-phase contains only fine-grained Ni-rich taenite. In both particle types there are also fine-grained phosphate, troilite, and silicate. Both particle types have mostly rounded to subrounded form. Author (revised)

ON POSSIBILITY OF DIAMOND FORMATIONS IN RADIATION PROCESS Abstract Only c90

A. V. Fisenko, L. F. Semjonova, L. N. Bolsheva, T. V. Grachjova, A. B. Verchovsky, and Yu. A. Shukolyukov *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 483-484 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The possibility of diamond formation in radiation processes was checked by studying diamond contents in carburanium sample. The diamonds were not found and this result is discussed. At present one possible process of formation of nanometer-size diamond crystals in some meteorites and Earth's diamonds (carbonado), the radiation mechanism, is suggested: the formation of diamonds from carbonaceous matter in tracks of U fragment fissions and heavy fragmentation due to the action of energetic particles of cosmic rays. Bjakov et. al. have carried out the calculations and shown that the volume of formed diamonds in carbonaceous chondrites by radiation processes corresponds to discovery of diamond volume in chondrites. The discovery by Ozima et. al. of the unsupported fission of Xe and Kr in carbonado supports the supposition that carbonado could be formed by radiation processes. The possibility of diamond formation in radiation processes leads to the study of diamond contents in Earth's samples enriched by uranium and carbon. The attempt to release the diamonds from carburanium was undertaken. Author (revised)

THE CARBON ISOTOPIC COMPOSITION OF NOVO UREI DIAMONDS Abstract Only c90

A. V. Fisenko, L. F. Semjenova, A. B. Verchovsky, S. S. Russell, and C. T. Pillinger (Open Univ., Milton, England.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 485-486 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The carbon isotopic composition of diamond grains isolated from the Novo Urei meteorite are discussed. A diamond separate was obtained from 2g of whole rock using the chemical treatments described aimed at obtaining very pure diamond. X ray diffraction of the residue, which represented 5000 ppm of the parent mass, indicated only the presence of the desired mineral. The diamond crystals were 1-30 microns in diameter, and some grains had a yellow color. The chemical treatments were followed by a size separation to give a 1-10 microns and a 5-30 microns fraction, which were named DNU-1 and DNU-2, respectively. Author (revised)

THE FRACTIONATION OF NOBLE GASES IN DIAMONDS OF CV3 EFREMOVKA CHONDRITE Abstract Only c25

A. V. Fisenko, A. B. Verchovsky, L. F. Semjonova, and Yu. A. Shukolyukov *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 487-488 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

It was shown that in diamonds of Efremovka CV3 the noble gases with normal isotopic compositions are fractionated in different degree while the correlation of isotopic anomalous components is nearly constant. Some data for noble gases in DE-4 sample of Efremovka chondrite are considered. In contrast to DE-2 sample the DE-4 was treated except conc. $HClO_4$, 220 C in addition with mixture of conc. $H_2SO_4+H_3PO_4$ (1:1), 220 C, twice. Noble gases analysis were performed in Germany at Max Plank Institute fur Chemie. Noble gases were released by oxidation of samples at stepped heating from 420 C to 810 C and by pyrolysis at 580, 590, and 680 C. Author (revised)

CRONSTEDTITE AND IRON SULFIDE MINERALOGY OF CM-TYPE CARBONACEOUS CHONDRITES FROM CRYOGENIC MOESSBAUER SPECTRA Abstract Only c90

Duncan S. Fisher and Roger G. Burns *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 489-490 (For primary document see N94-12015 01-91)
(Grants NAGw-2049; NAGw-2220)
Avail: CASI HC A01/MF A06

Determinations of oxidation states and the crystal chemistry of iron-bearing minerals in CM meteorites by Moessbauer spectroscopy are complicated by thermally-induced electron hopping in cronstedtite and by ill-defined contributions from the hydrous iron sulphide phase believed to be tochilinite. Moessbauer spectral measurements at 30 K of several cronstedtite and tochilinite specimens have enabled modal proportions of these minerals, as well as Fe(3+)/Fe(2+) ratios, to be determined quantitatively for a suite of CM-type carbonaceous chondrites that included Murchison, Murray, Cold Bokkeveld, ALH 83100, and LEW 90500. NMR SPECTROSCOPY OF EXPERIMENTALLY SHOCKED SINGLE CRYSTAL QUARTZ: A REEXAMINATION OF THE NMR SHOCK BAROMETER Abstract Only c25

P. S. Fiske, A. J. Gratz (Lawrence Livermore National Lab., CA.), and W. J. Nellis (Lawrence Livermore National Lab., CA.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 491-492 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Cygan and others report a broadening of the Si-29 nuclear magnetic resonance (NMR) peak for synthetic quartz powders with increasing shock pressure which they propose as a shock wave barometer for natural systems. These results are expanded by studying single crystal quartz shocked to 12 and 33 GPa using the 6.5 m two-stage light-gas gun at Lawrence Livermore National Laboratories. Our NMR results differ substantially from those of Cygan and others and suggest that the proposed shock wave barometer may require refinement. The difference in results between this study and that of Cygan and others is most likely caused by different starting materials (single crystal vs. powder) and different shock loading histories. NMR results from single crystal studies may be more applicable to natural systems. Author (revised)

ORGANIC MATTER ON THE EARLY SURFACE OF MARS: AN ASSESSMENT OF THE CONTRIBUTION BY INTERPLANETARY DUST Abstract Only
G. J. Flynn *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 493-494 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Calculations by Anders and Chyba et al. have recently revived interest in the suggestion that organic compounds important to the development of life were delivered to the primitive surface of the Earth by comets, asteroids or the interplanetary dust derived from these two sources. Anders has shown that the major post-accretion contribution of extraterrestrial organic matter to the surface of the Earth is from interplanetary dust. Since Mars is a much more favorable site for the gentle deceleration of interplanetary dust particles than is Earth, model calculations show that biologically important organic compounds are likely to have been delivered to the early surface of Mars by the interplanetary dust in an order-of-magnitude higher surface density than onto the early Earth. Using the method described by Flynn and McKay, the size frequency distribution, and the atmospheric entry velocity distribution of IDP's at Mars were calculated. The entry velocity distribution, coupled with the atmospheric entry heating model developed by Whipple and extended by Fraundorf was used to calculate the fraction of the particles in each mass decade which survives atmospheric entry without melting (i.e., those not heated above 1600K). The incident mass and surviving mass in each mass decade are shown for both Earth and Mars. Author (revised)

DEPLETIONS OF SULFUR AND/OR ZINC IN IDPs: ARE THEY RELIABLE INDICATORS OF ATMOSPHERIC ENTRY HEATING? Abstract Only c90
G. J. Flynn, S. R. Sutton (Chicago Univ., IL.), S. Bajt (Chicago Univ., IL.), W. Kloeck (Westfaelische Wilhelms Univ., Muenster, Germany.), K. L. Thomas (Lockheed Corp., Houston, TX.), and L. P. Keller (National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, TX.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 497-498 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

The degree of heating of interplanetary dust particles (IDP's) on Earth atmospheric entry is important in distinguishing cometary particles from main-belt asteroidal particles. Depletions in the volatile elements S and Zn were proposed as chemical indicators of significant entry heating. The S and Zn contents of cosmic dust particles were correlated with physical indicators of atmospheric entry heating, such as the production of magnetite and the loss of solar wind implanted He. The results indicate that the Zn content of IDP's is a useful indicator of entry heating, but the S content seems to be less useful. Author (revised)

NEW LOW-NI (IGNEOUS?) PARTICLES AMONG THE C AND C? TYPES OF COSMIC DUST Abstract Only c90
G. J. Flynn, S. R. Sutton (Chicago Univ., IL.), S. Bajt (Chicago Univ., IL.), and W. Kloeck (Westfaelische Wilhelms Univ., Muenster, Germany.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 499-500 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Low-Ni particles with major element abundances, optical properties, and morphologies sufficiently similar to chondritic interplanetery dust particles (IDP's) to receive JSC Cosmic Dust Catalog classifications of C or C?-types were shown to have trace element contents and mineralogies similar to igneous material. Examination of the JSC Catalog EDX spectra by Cooke et al. has shown that 13 percent of the C-type and 38 percent of the C?-type particles are potentially low-Ni particles. Two new low-Ni particles were identified, and it was shown that an additional fragment from the L2002*C cluster has an igneous composition. A newly analyzed fragment of the W7066*A cluster has a chondritic composition. The W7066*A cluster is important because it has yielded a fragment of igneous composition and another fragment having high concentrations of He and Ne suggesting an extraterrestrial origin. MASS AND SPATIAL DISTRIBUTION OF CARBONACEOUS COMPONENT IN COMET HALLEY Abstract Only c90
M. Fomenkova and S. Chang *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 501-502 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Cometary grains containing large amounts of carbon and/or organic matter were discovered by in situ measurements of cometary dust composition during VEGA and GIOTTO fly-by missions. In accordance with the classification for the data of PUMA-1 and PUMA-2 mass-spectrometers on board the VEGA spacecraft, particles with a ratio of C to any rock-forming element (Mg, Si, Fe, Ca etc.) greater than 10, were categorized as CHON. There are 464 such particles in PUMA-1 data and 51 in PUMA-2 data. Application of cluster analysis to these grains revealed several distinct compositional classes, namely: (H,C,N,O), (H,C,N), (H,C), (H,C,O), (C,N), (C,O), (C,N,O), and (C). Similar classes were identified among particles analyzed by PIA. Also, about a third of all particles fell into groups (H) and (O) characterized by abundances of these elements beyond chemically reasonable limits. Author (revised)

PRIMITIVE SNC PARENT MAGMAS AND CRYSTALLIZATION: LOW PH2O EXPERIMENTS Abstract Only c90
D. J. Ford and M. J. Rutherford *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 503-504 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

SNC meteorites are generally believed to present one of the best opportunities to study the composition and petrogenesis of Mars magmas. The crystallization ages, noble gas content, oxygen isotopic composition, and shocked minerals of the meteorites are consistent with a Martian origin. The samples range from dunite to clinopyroxenite to microgabbro. Efforts by researchers to determine parental magmas for the more primitive SNC meteorites have been complicated by crystal accumulation and possible melt segregation and removal. This has resulted in a range of parent magma estimates, although all appear to be Fe-rich and Al-poor. One major objective is to refine the Chassigny parent magma estimate by forcing olivine + clinopyroxene saturation upon the proposed melt composition. EETA 79001 magma compositions are also being investigated to determine the parent magma and the origin of the coarse-grained olivine and orthopyroxene megacrysts. Low pressure experiments with small but finite P(sub H2O) are being utilized to facilitate equilibrium, and to simulate the H2O indicated for these magmas. The presence of small (0.5-1.0 wt percent) amounts of H2O in SNC magmas appears to be required by the occurrence of hydrous minerals and textures in melts trapped by growing phenocrysts. This evidence for hydrous melts occurs in all SNC's except EETA 79001 and ALHA 77005, where the inclusion textures were obscured

by shock effects. The lack of hydrous minerals or low temperature melts in the intercumulus regions of these rocks suggests that final emplacement was sufficiently close to the surface to allow degassing as the magma equilibrated with the low P atmosphere. Any H2O left in intercumulus phases would also tend to be lost during impact heating. Thus, although the bulk H2O of SNC's is very low, it is believed that this is explained by the near Mars surface emplacement of SNC magmas and by shock effects. Magmatic processes involving H2O need to be examined in order to characterize SNC magmas immediately prior to their final emplacement.

PHASE TRANSITIONS AND 2D SPHERICAL CONVECTION IN A LARGE ICY SATELLITE Abstract Only **c90**
O. Forni, C. Federico (Perugia Univ., Italy.), and A. Coradini (Consiglio Nazionale delle Ricerche, Rome, Italy.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 505-506 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Three ice phase transitions, based on experimental and theoretical results, were incorporated into a 2D spherical convection model. These phase transitions are the exothermic Ice 1-2, the endothermic Ice 2-6, and the exothermic Ice 6-8 phase transitions. The fluid is assumed isoviscous and the anelastic liquid formulation was used. The object is an icy satellite whose physical characteristics resemble those of Ganymede or Callisto. Structural models, similar to those of Mueller and McKinnon, with different core sizes, i.e. with different degree of differentiation were studied. The shells, i.e. the mantle of the satellite, is heated both internally and from below to account for the decaying radiogenic heating and the heat flow from the solid core. The lower boundary of the mantle is rigid and isothermal, the upper boundary is isothermal. Calculations with rigid and shear stress free upper boundary are carried out in order to assess the role of the different boundary conditions. Two different Rayleigh numbers, depending on the assumed value of the viscosity, were used in the calculations and the thermal evolution of the satellite was studied. The suit of calculations presented demonstrates that phase transition cannot be ignored when the thermal evolution of a large icy satellite has to be studied. The importance of the construction of the realistic phase diagram for ice was also documented. On the other hand the degree of differentiation, simulated with the structures with different core's radius does not seem to drastically influence the overall behavior of the convective activity. Within the limits of our simulations, the post-accretional evolution seems to be independent on the degree of primordial differentiation. Author (revised)

DO LARGE IMPACT BASINS IN THE SOUTHERN HEMISPHERE OF MARS CONTROL THE DISTRIBUTION OF POLAR STRUCTURES AND DEPOSITS? Abstract Only
Herbert Frey and Anne-Marie Reidy (Maryland Univ., College Park.) *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 509-510 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Among the outstanding problems in Martian geology are the cause of the off-axis and asymmetric distribution of the southern polar layered terrain and residual ice deposits and the cause of the orientation of scarps, valleys, and re-entrant canyons which occur there. A perhaps related problem region is the apparently small number of large (D greater than 500 km) impact basins seen in the relatively well-preserved cratered terrain of the south polar region. Previously only the 850 km wide South Polar Basin was easily recognized. The south polar region was mapped in detail, searching for evidence of ancient, highly degraded impact basins that may have escaped earlier notice, for two reasons: (1) to determine whether the apparent absence of large impact basins is due to incomplete mapping and recognition or a fundamental characteristic of the Martian crust related to the origin of the Martian crustal dichotomy, and (2) to determine whether ancient impact basins, if they exist, exert some control on the distribution of volcanic and polar deposits in the southern hemisphere and on the topography on which these deposits lie. Several promising candidates, including a large pre-Hellas basin in the Malea Planum region and an older but comparably sized basin overlapping South Polar, were previously described. Concentration is on the possible influence of the candidate basins in localizing the asymmetric distribution of polar deposits and in controlling the orientation of structures found within these deposits.

FREE-AIR AND BOUGUER GRAVITY ANOMALIES AND THE MARTIAN CRUSTAL DICHOTOMY Abstract Only
Herbert Frey, Bruce G. Bills, Walter S. Kiefer, R. Steven Nerem, James H. Roark, and Maria T. Zuber *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 511-512 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Free-air and Bouguer gravity anomalies from a 50x50 field, derived from re-analysis of Viking Orbiter and Mariner 9 tracking data and using a 50x50 expansion of the current Mars topography and the GSFC degree 50 geoid as the equipotential reference surface, with the Martian crustal dichotomy are compared. The spherical harmonic topography used has zero mean elevation, and differs from the USGS maps by about 2 km. In this field the dichotomy boundary in eastern Mars lies mostly at -1 to -2 km elevation. Bouguer gravity anomalies are shown on a map of Noachian, Hesperian, and Amazonian age terrains, simplified from current geologic maps. The map is centered at 300 deg W to show the continuity of the dichotomy boundary. Contour interval is 100 mgals. Gravity and topography were compared along approximately 40 profiles oriented parallel to the dichotomy boundary topographic gradient, to determine how the geophysical character of the boundary changes along its length and what this implies for its origin and development. NEW MARS FREE-AIR AND BOUGUER GRAVITY: CORRELATION WITH TOPOGRAPHY, GEOLOGY AND LARGE IMPACT BASINS Abstract Only
Herbert Frey, Bruce G. Bills, Walter S. Kiefer, R. Steven Nerem, James H. Roark, and Maria T. Zuber *In* Lunar and Planetary Inst., Twenty-fourth Lunar and Planetary Science Conference. Part 1: A-F 1993 p 513-514 (For primary document see N94-12015 01-91)
Avail: CASI HC A01/MF A06

Free-air and Bouguer gravity anomalies from a 50x50 field (MGM635), derived at the Goddard Space Flight Center, with global topography, geology, and the distribution of large impact basins was compared. The free-air gravity anomalies were derived from re-analysis of Viking Orbiter and Mariner 9 tracking data and have a spatial resolution of 250-300 km. Bouguer anomalies were calculated using a 50x50 expansion of the current Mars topography and the GSFC degree 50 geoid as the equipotential reference surface. Rotational flattening was removed using a moment of inertia of 0.365 and the corrections from Table B2 of Sleep and Phillips. Crustal density and mean density were assumed to be 2.9 and 3.93 gm/cm(sup 3). The spherical harmonic topography used has zero mean elevation, and differs from the USGS maps by about 2 km. Comparisons with global geology use a simplified map with about 1/3 the number of units on the current maps. For correlation with impact basins, the recent compilation by Schultz and Frey was used. AN INTERFEROMETRIC SPECTRAL MAPPER FOR THE CASSINI MISSION TO SATURN AND TITAN Final Report
William Hayden Smith 31 Oct. 1991 5 p
(Grant NAGw-1801)
(NASA-CR-193805; NAS 1.26:193805) Avail: CASI HC A01/MF A01

The research reported resulted in a detailed proposal for the Cassini Mission that addressed fundamental atmospheric structure and composition questions for both Saturn and Titan. Due to the brief time available between the initiation of the research and the proposal date, it was necessary to develop the science goals in close synchronicity with the instrument design. A major goal of the program was to acquire, implement, and test SWIR and MWIR arrays suitable for use with the DIGITAL ARRAY SCANNED INTERFEROMETERS, (DASI's), for the extended goal of developing DASI's for a range of spectral mapping research in solar system exploration. These goals were all reached or exceeded in the course of this work. Author (revised)

INTERDISCIPLINARY SCIENTIST PARTICIPATION IN THE PHOBOS MISSION Final Report, 15 Sep. 1989 - 14 Jun. 1992
14 Jun. 1992 5 p
(Grant NAGw-1868)
(NASA-CR-193715; NAS 1.26:193715) Avail: CASI HC A01/MF A01

Data was acquired from VSK (2 wide-angle visible-NIR TV cameras at 0.4 to 0.6 micrometers and 0.8 to 1.1 micrometers, and a narrow-angle TV camera), KRFM (10-band UV-visible spectrometer at 0.3 to 0.6 micrometers and a 6-band radiometer at 5-50 micrometers), and ISM (a 128-channel NIR imaging spectrometer at 0.8 to 3 micrometers). These data provided improved mapping coverage of Phobos; improved mass, shape, and volume determinations, with the density shown to be lower than that of all known meteorites, suggesting a porous interior; evidence for a physically, spectrally and possibly compositionally heterogeneous surface; and proof that the spectral properties do not closely resemble those of unaltered carbonaceous chondrites, but show more resemblance to the spectra of altered mafic material. For Mars, the data show that the underlying rock type can be distinguished through the global dust cover; that the spectral properties and possibly composition vary laterally between and within the geologic provinces; that the surface physical properties vary laterally, and in many cases, the boundaries coincide with those of the geologic units; and the acquired data also demonstrate the value of reflectance spectroscopy and radiometry to the study of Martian geology. ANALYSIS OF IRAS SOLAR SYSTEM DUST DATA Final Technical Report, 1 Jun. 1989 - 31 Dec. 1991
S. F. Dermott and P. D. Nicholson 1991 5 p
(Grant NAG5-1261)
(NASA-CR-193704; NAS 1.26:193704) Avail: CASI HC A01/MF A01

Data in the Infrared Astronomical Satellite (IRAS) Zodiacal History File were analyzed to extract dust band locations and peak brightness measurements from approximately 1,000 individual IRAS scans. The study had three goals. One was to show that the prominent solar system dust bands are associated with Hirayama asteroid families and thus that collisions between asteroids account for a significant fraction of the particles in the zodiacal cloud. Recent work suggests that while the Hirayama families are a major source of the dust in the bands, there may also be contributions from two or three smaller, more recently recognized asteroid families. A second goal was to show that there is evidence in the IRAS dust data for the transport of particles from asteroid belt to the Earth by Poynting-Robertson light drag and thus account for the fact that asteroid particles are collected in the Earth's stratosphere. Results of the study will confirm the location of the dust bands within the inner asteroid belt, and show conclusively that the material seen by IRAS is now spread over a wide range of distances from the sun. The third goal was to construct a model of the background zodiacal cloud that satisfies the proper dynamical constraints. Figures are provided to show the scans processed to remove zodiacal background and Galactic signals, and the resulting polynomial fits to the 25 micron scan. The latter provided objective estimates of band widths, peak locations, and peak fluxes. Modelling and analysis of the resulting band data has been presented at several conferences and is the subject of a number of forthcoming papers. CASI

SMM X RAY POLYCHROMATOR Final Report, Jun. 1988 - Jul. 1993
J. L. R. Saba 7 Jul. 1993 52 p
(Contract NAS5-30431)
(NASA-CR-193282; NAS 1.26:193282) Avail: CASI HC A04/MF A01

The objective of the X-ray Polychromator (XRP) experiment was to study the physical properties of solar flare plasma and its relation to the parent active region to understand better the flare mechanism and related solar activity. Observations were made to determine the temperature, density, and dynamic structure of the pre-flare and flare plasma as a function of wavelength, space and time, the extent to which the flare plasma departs from thermal equilibrium, and the variation of this departure with time. The experiment also determines the temperature and density structure of active regions and flare-induced changes in the regions. Author (revised)

YOHKOH BRAGG CRYSTAL SPECTROMETER LIGHT CURVES FOR CA XIX (3.1631-3.1912A): 1 OCTOBER 1991 - 30 SEPTEMBER 1992
John T. Mariska, R. D. Bentley, and C. D. Pike 4 Apr. 1993 195 p
(AD-A266090; NRL/MR/7673-93-7313) Avail: CASI HC A09/MF A03

This Memo Report summarizes the data produced during the first year of operation by the Bragg Crystal Spectrometer (BCS) on the Yohkoh spacecraft. Each page shows the total count rate in the Ca XIX channel of the BCS for a single day. This channel nominally observes the Sun in the wavelength range from 3.1631 to 3.1912 A. These plots are useful for identifying flare data for further analysis and for determining the data file name and tape name that contain the data. DTIC

[COSMOLOGICAL GAMMA-RAY BURST MODEL] Final Report
J. J. Brainerd 1993 7 p
(Grant NAG5-2056)
(NASA-CR-193368; NAS 1.26:193368) Avail: CASI HC A02/MF A01

A cosmological gamma-ray burst model that reproduces the observed gamma-ray spectra was developed. This model, which is an outgrowth of work on synchrotron emission from cosmological sources, creates the observed spectra from a power law spectrum through Compton attenuation in dense molecular clouds. It restricts the burst source to the centers of galaxies, and it is easily tested through comparisons with time dependent burst spectra. Dr. Brainerd continued development of a Monte Carlo code that tracks the random walk of a gamma-ray through a plasma in a strong magnetic field and used this code to show that a two temperature plasma in a strong magnetic field can suppress soft x-ray emission. NONPERTURBATIVE METHODS IN HZE ION TRANSPORT
John W. Wilson, Francis F. Badavi (Christopher Newport Coll., Newport News, VA.), Robert C. Costen, and Judy L. Shinn Washington Aug. 1993 27 p
(RTOP 199-45-16-11)
(NASA-TP-3363; L-17241; NAS 1.60:3363) Avail: CASI HC A03/MF A01

A nonperturbative analytic solution of the high charge and energy (HZE) Green's function is used to implement a computer code for laboratory ion beam transport. The code is established to operate on the Langley Research Center nuclear fragmentation model used in engineering applications. Computational procedures are established to generate linear energy transfer (LET) distributions for a specified ion beam and target for comparison with experimental measurements. The code is highly efficient and compares well with the perturbation approximations. Author

A PROPOSED PERFORMANCE INDEX FOR GALACTIC COSMIC RAY SHIELDING MATERIALS
John W. Wilson, J. S. Wood, Judy L. Shinn, Francis A. Cucinotta, and John E. Nealy Washington Aug. 1993 10 p
(RTOP 592-43-21-01)
(NASA-TM-4444; L-17199; NAS 1.15:4444) Avail: CASI HC A02/MF A01

In past studies, the reductions in absorbed dose and dose equivalent due to choice of material composition have been used to indicate shield effectiveness against exposure to galactic cosmic rays. However, these quantities are highly inaccurate in assessing shield effectiveness for protection against the biological effects of long-term exposure to the galactic heavy ions. A new quantity for shield performance is defined that correlates well with cell killing and cell transformation behind various shield thicknesses and materials. In addition, a relative performance index is identified that is inversely related to biological injury for different materials at a fixed shield mass and is directly related to the ratio of the fourth- and the second-order linear energy transfer (LET) moments. MODELS OF NEPTUNE'S SMOOTH RECURRENT RADIO EMISSION Final Report, 4 June 1992 - 9 Jul. 1993
Constance Sawyer 9 Jul. 1993 14 p
(Contract NASw-4697)
(NASA-CR-193283; NAS 1.26:193283) Avail: CASI HC A03/MF A01

The quantitative response of the Planetary Radio Astronomy (PRA) instrument to a wave with polarization ellipse of arbitrary shape and orientation, arriving at the antennas from any direction, can be determined. This capability is used to model the time variation of intensity and circular polarization over a range of radio frequencies for proposed radio-source locations and emission characteristics at Neptune. At frequencies below 400 kHz the observed variation of intensity, polarization, and phase are closely simulated in an offset tilted dipole magnetic field by conjugate sources at midlatitude with filled emission cones. The phase of emission at higher frequencies is reproduced by sources at lower latitude. Modeled wide-cone emission does not reach the spacecraft at the observed phase nor have the polarization sense observed before closest approach. Source-surface maps of apparent polarization for the period before closest approach when instrumental response is especially sensitive to source location is presented. The method is capable of extension to more realistic models of the magnetic field. Author (revised)

POST-LAUNCH ANALYSIS OF DATA FROM THE HIGH ENERGY ASTROPHYSICAL OBSERVATORY HEAVY NUCLEI EXPERIMENT (HEAO-C3) Final Report, period ending 31 Mar. 1992
E. C. Stone 1992 4 p
(Grants NAGw-1930; NAGw-1934; NAGw-1954)
(NASA-CR-193513; NAS 1.26:193513) Avail: CASI HC A01/MF A01

The Final Report on the continuing analysis of data from the Heavy Nuclei Experiment (HNE), flown on the HEAO-3 mission, is presented. The HNE was designed to measure the elemental abundances of relativistic cosmic ray nuclei covering the charge range 17 is less than or equal to Z is less than or equal to 130. The result of these measurements is significant to the study of nucleosynthesis, the origin, acceleration, and propagation of cosmic ray nuclei, and the properties of the interstellar medium. SEARCH FOR STRUCTURES IN THE COSMIC MICROWAVE BACKGROUND RADIATION M.S. Thesis, 1992 [APLICACAO DE UM METODO PARA DETECCAO DE FLUTUACOES NA RADIACAO COSMICA DE FUNDO]
Angelica deOliveiraCosta Jan. 1993 90 p In PORTUGESE
(INPE-5491-TDI/508) Avail: CASI HC A05/MF A01

We applied a method to search for fluctuations in the cosmic microwave background radiation based on the assumption that such fluctuations can be described by a random Gaussian field. We used two maps, one at 3.3 mm and another obtained combining the 3.3 mm and 12 mm maps, both experiments had beam size of 7 degrees (FWHM). Although two regions, one hot and another cold, have been detected in the 3.3 mm data set at 2 sigma (or 95.45% of C.L.), they cannot be considered as Hot or Cold Spots because both structures were smaller than the region covered by the beam size.
